June 26, 2001

Abstract

This note describes an analysis of beam charge asymmetries for the e1c running period which ran January to April, 1999. This analysis was undertaken to investigate possible beam asymmetries which would influence extracted analyzing powers. Elastic e-p scattering has no asymmetry and thus serves as an excellent monitor of beam charge asymmetry. 2.567 GeV, 4.247 GeV, and 4.462 GeV data were analyzed. The majority of asymmetries are less than 1% for a single run, averaging to $0.348\text{E-}03 \pm 0.149\text{E-}03$ for the complete set of analyzed runs.

1 Procedure

The analysis was performed on the e1c ntuples. Spin-sorted W projections were made, elastic peaks were summed, and beam charge asymmetries were formed from the elastic sums. A sample W spectrum is shown in Figure 1 with summing gate. Asymmetries were calculated as:

$$A = \frac{Y_+ - Y_-}{Y_+ + Y_-}$$

with statistical uncertainties given by:

$$\Delta A = \sqrt{\frac{4Y_+Y_-}{(Y_+ + Y_-)^3}}$$

where Y_+ (Y_-) is the yield for the positive (negative) helicity state.

Helicity information was taken from the ntuple variable *evntclas* which includes both helicity and trigger bit information. For the 2.567 and 4.247 GeV runs, *evntclas* = 1 & 2 was taken to be helicity state 1 and *evntclas* = 4 & 5 was taken to be helicity state 2. The level 2 trigger was introduced during the e1c running. As a result the trigger bits changed and the *evntclas* states changed. *Evntclas* = 11 & 12 was taken to be helicity state 1 and *evntclas* = 14 & 15 was taken to be helicity state 2 for the 4.462 GeV runs. Sometimes it takes a while to get used to new things. This was true for the level 2 trigger. For runs 17591 to 17664, the wrong trigger file was loaded and *evntclas* changed again creating a sequence of values. We took helicity state 1 to be when *evntclas* = 1, 2, 11, 12, 21, & 22 and the helicity state 2 to be when *evntclas* = 4, 5, 14, 15, 24, & 25 for these runs. This is consistent with other helicity-dependent analyses.

Determining the sign of the asymmetry involves correlating the helicity states with positive and negative values. This depends both upon the status of the half-wave plate at the polarized ion source and the spin precession of the electrons in the accelerator. For the 2.567 and 4.247 GeV running, when the half-wave plate was IN (OUT) helicity state 1 (2) was positive. For the 4.462 GeV running, when the half-wave plate was OUT (IN) helicity state 1 (2) was positive. These effects were included in the analysis.

2 Results and Discussion

Gold runs for the 2.567 GeV, 4.247 GeV, and 4.462 GeV data sets were analyzed. The 4.056 GeV data were not analyzed as there was significant beam polarization contamination due to leak through from Hall C. Run 17708 and those following were

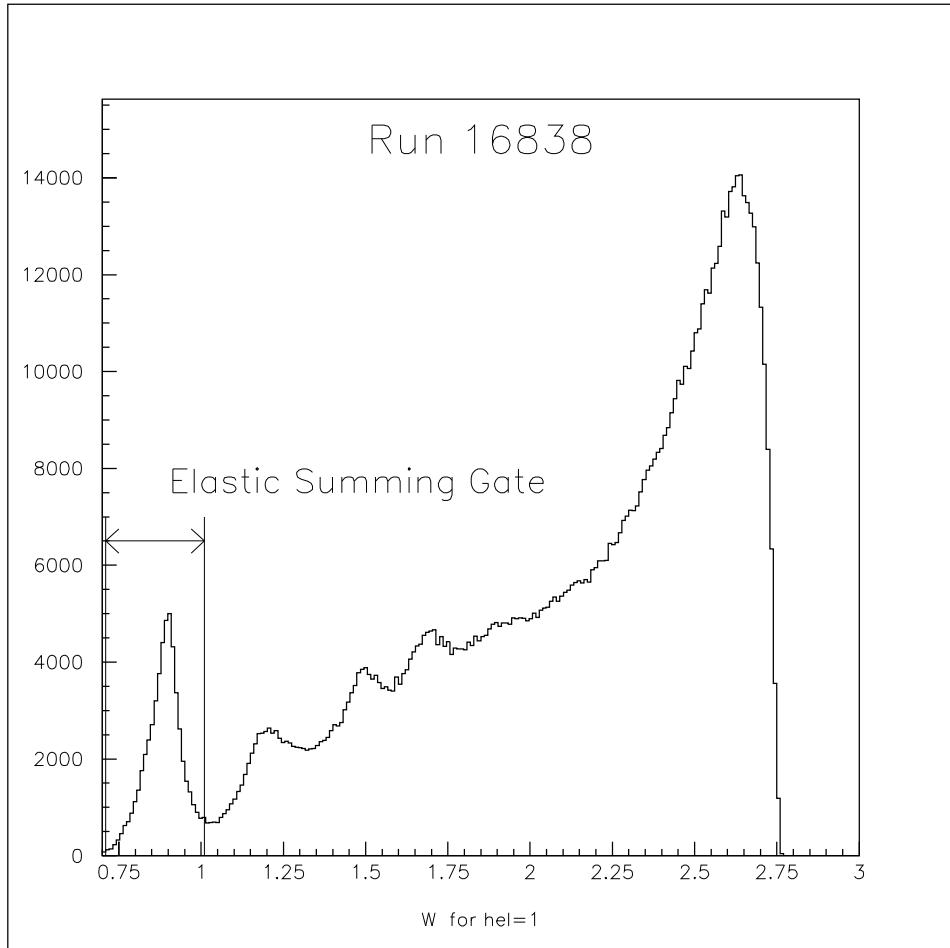

Figure 1: Typical W spectrum used in analysis. Summing region is indicated.

taken in delayed-polarization reporting mode and are not included in this report. This includes all of the 4.462 GeV / 2250 A running and part of the 4.462 GeV / 3375 A running. Complete sets of data for several runs was not available due to corruption of the tape media in the mass storage silo. These include runs 16704, 16705, 16707 16708 from the 2.567 GeV / 2250 A running and runs 16961 and 16976 from the 4.247 GeV / 3375 A running. These runs have not been included in this report. The averages for each kinematic setting are summarized in Table 2. Complete results for the remaining data sets are shown in Figures 2, 3, and 4 and presented in Tables 2, 3, 4, 5, and 6.

The majority of beam charge asymmetries are less than 1%, with an average asymmetry of less than 0.4% for each of the five kinematic settings, as can be seen in the tables. When averaged over the complete set of runs the asymmetry is 0.348E-03 \pm 0.149E-03. While not all of the results are consistent with zero, they are small enough to ignore at the current level of precision in CLAS. However, one trend may be of concern. There may be a correlation between half-wave plates and sign of the asymmetry in the 2.567 GeV data set. Most runs with half-wave plate IN are negative and most runs with half-wave plate OUT are positive at 2.567 GeV. This trend is not as apparent at the other energies.

Energy (GeV)	Torus (A)	Asymmetry	Statistical Uncertainty
2.567	1500	0.433E-03	0.178E-03
