

# Improving HMS Reconstruction: Alternate COSY Matrix Elements

**Eric Christy**

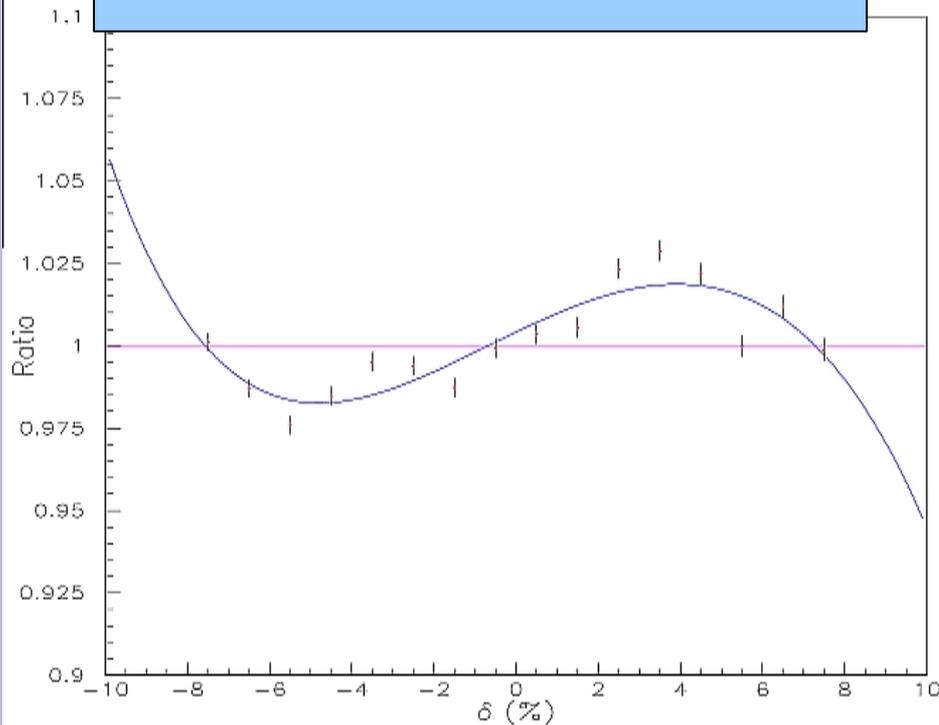

*Hall C Workshop – January 15, 2011*

# $\delta$ (dp/p) correction

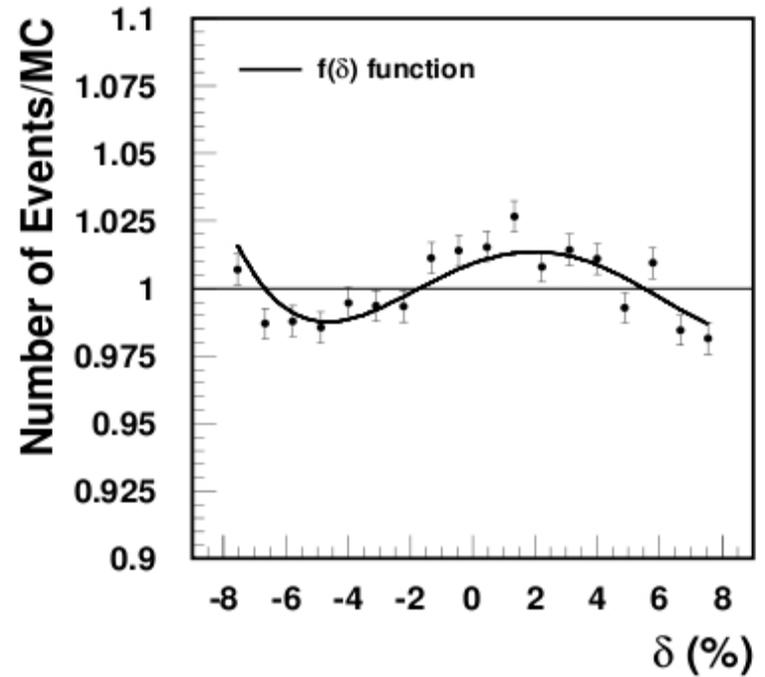

- Known for 10+ years that dp/p reconstruction looks to be over-fitted.
- Study with inclusive data/MC for wide range of kinematics and targets.
- Systematics in cross section model average out over over many targets, beam energies, and angles.  
  
=> Remaining differences versus dp/p are due to data/MC optics or acceptance.

# $\delta$ correction - 2

Fit from E94110 data (1999)  
E.C.

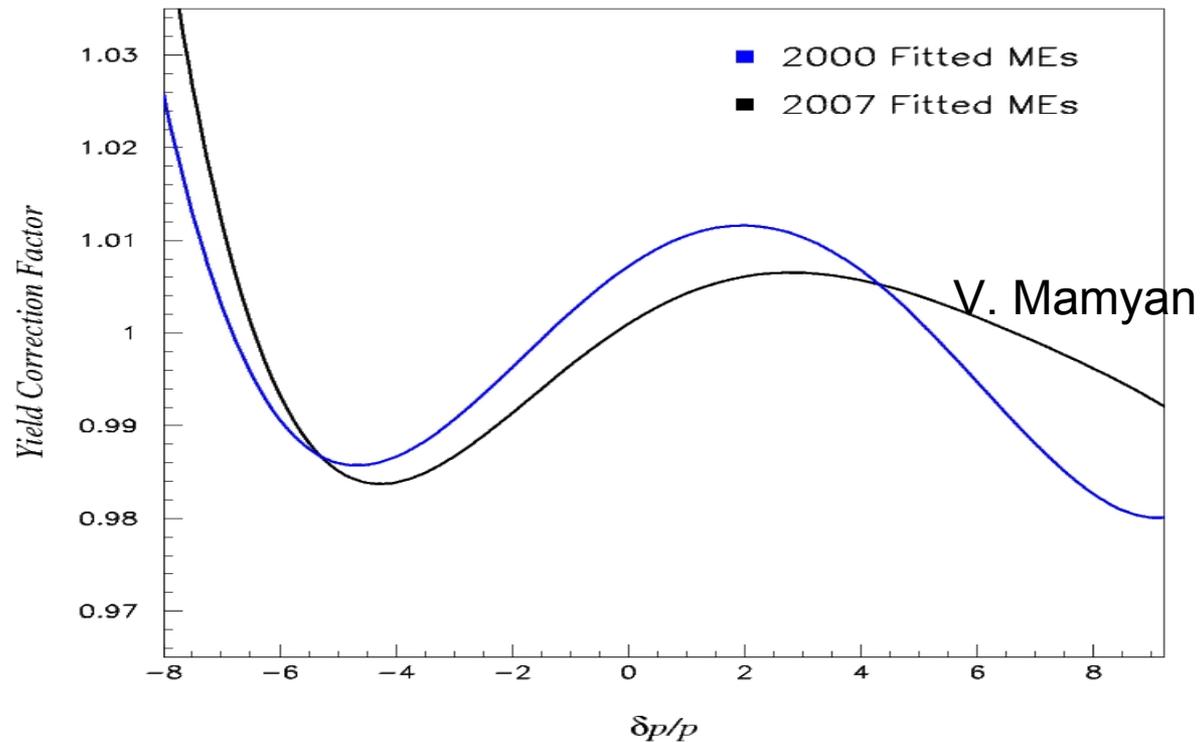

Fit from E99118 data (2000).  
V. Tvaskis dissertation

- Data from 1999-2003 showed very consistent correction factor
- Can be explained by small ( $< 4 \times 10^{-4}$ ) over fitting of  $\delta$  reconstruction MEs.

# Then and Now

- Small shift, but general shape consistent.
- Difference due to small 2007 DC shift ( $\sim 0.5$  mm)?

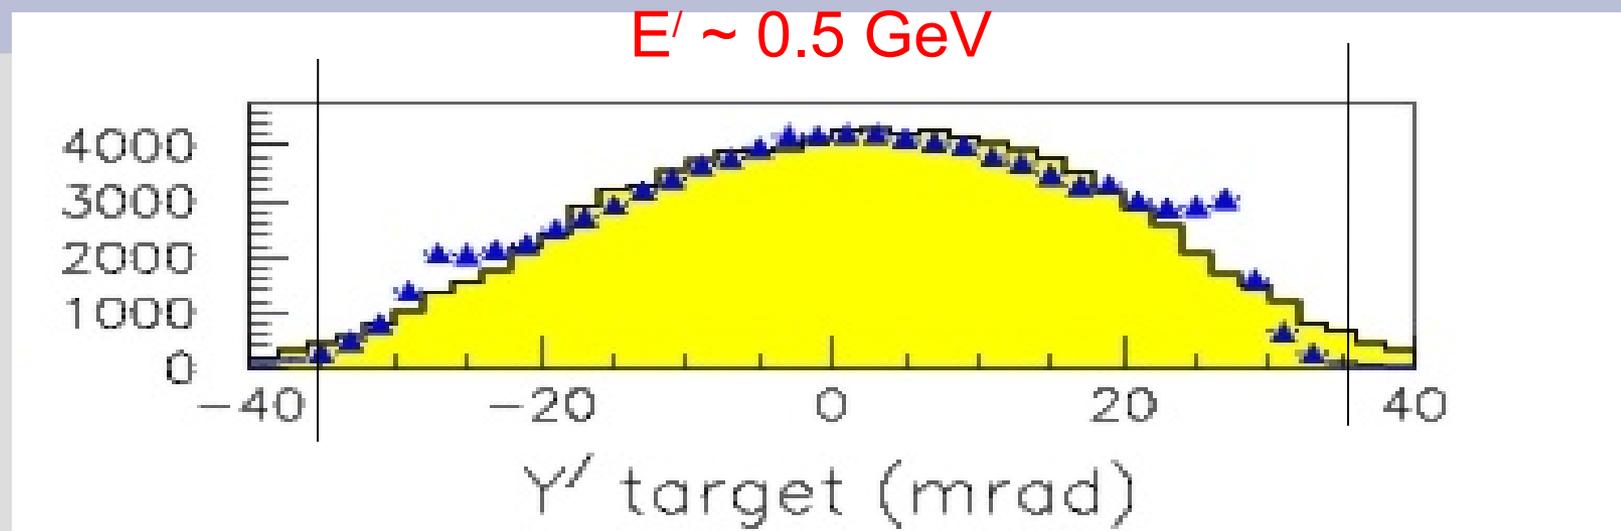

**But ...**

From 2003-2005 we also needed to deal with large multiple scattering at thick HMS exit window.

**(20 mil Titanium at that time)**

# Reconstruction Problem at Low $E'$

(Already discussed at previous workshops)

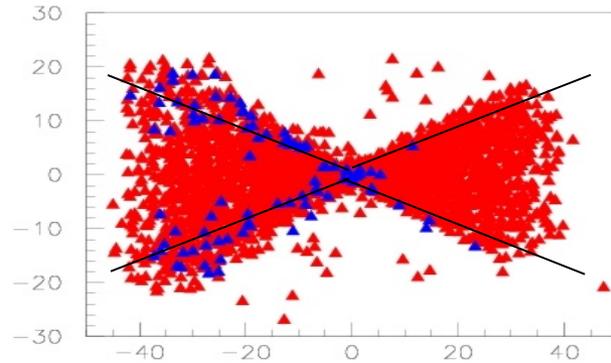

- Large multiple scattering caused by thick HMS exit window (20 mil Titanium).
- Events in tails are reconstructed at  $Y' \sim \pm 28 \text{ mrad}$  for **Data**.

***Fitted reconstruction matrix elements have anomalous behavior for tails.***

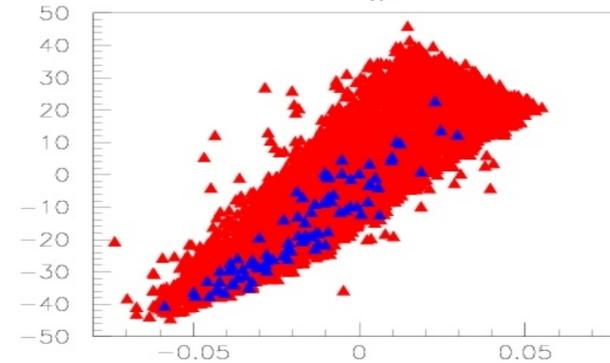

Focal plane is populated in area for which the fitted MEs are not well constrained.

# Cut on artifact region in $Y'_{tar}$

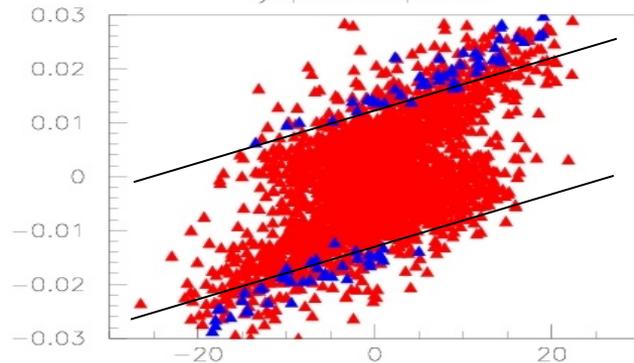

Blue – MC  $\text{abs}(Y'_{tar}) > 35 \text{ mrad}$

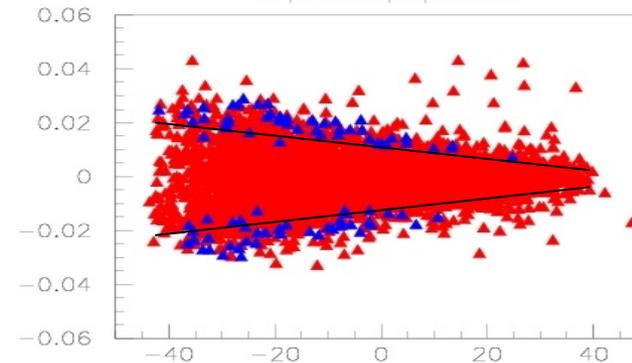

yfp.vs.xfp.dat

xfp.vs.xfp.dat

ypfp.vs.yfp.dat

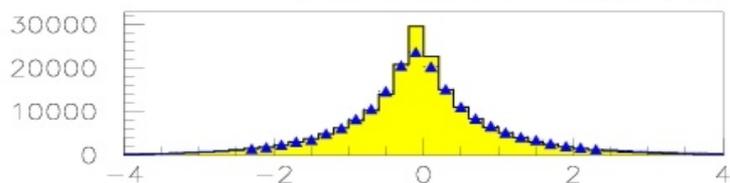

ypfp.vs.xfp.dat

Place cuts on data falling in the intersection of these regions

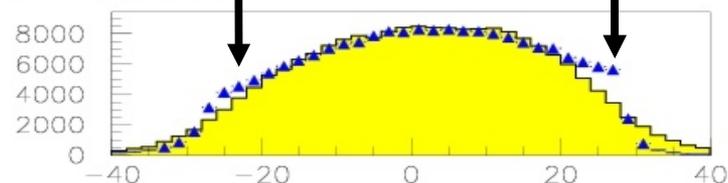

# Before Focal Plane Cuts

Run = 53320, Target = 4

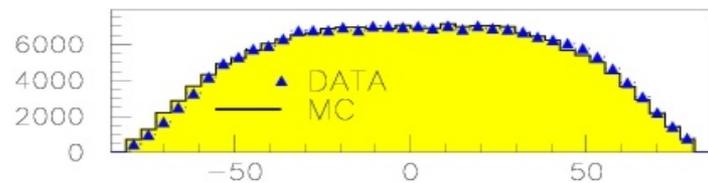

$E = 2.3476$ ,  $E' = 0.5137$ ,  $\Theta = 30.011$

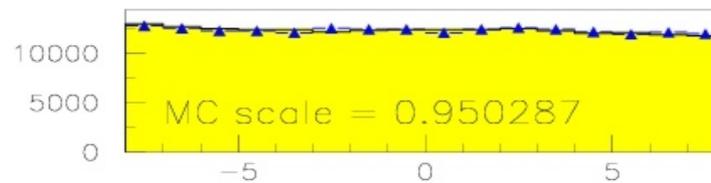

Y target (cm)

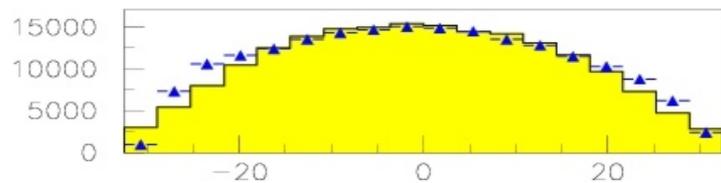

$Y'$  target (mrad)

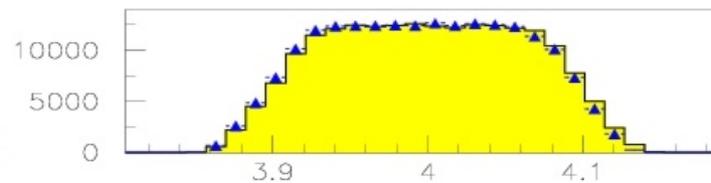

$X'$  target (mrad)

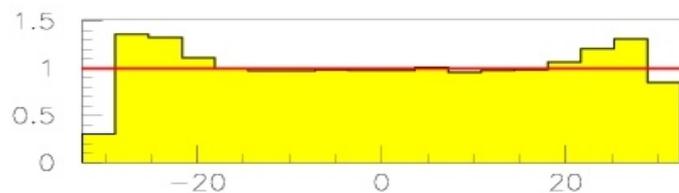

$\delta p/p$  (%)

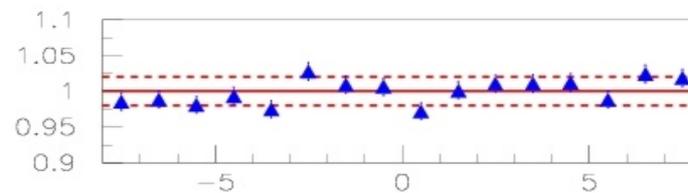

$\Theta - \Theta_c$  (mrad)

$W^2$  ( $\text{GeV}^2$ )

$\Theta - \Theta_c$  (mrad) (Ratio Data/MC)

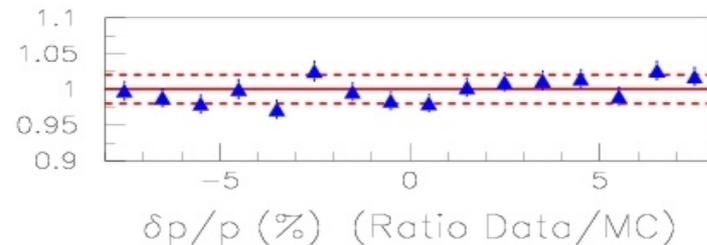

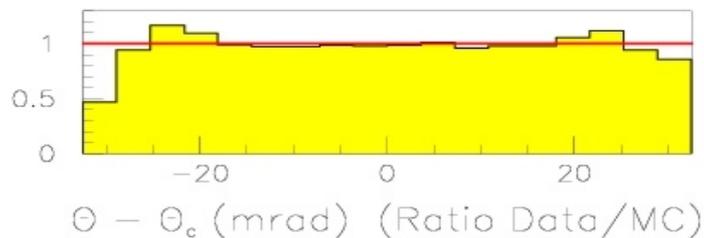

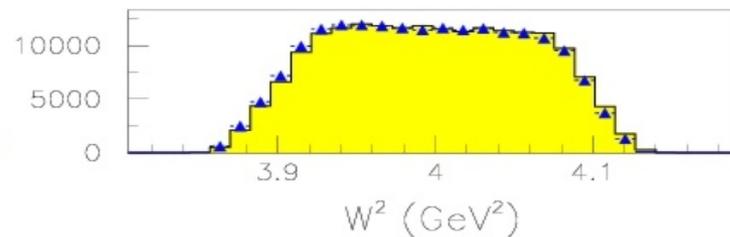

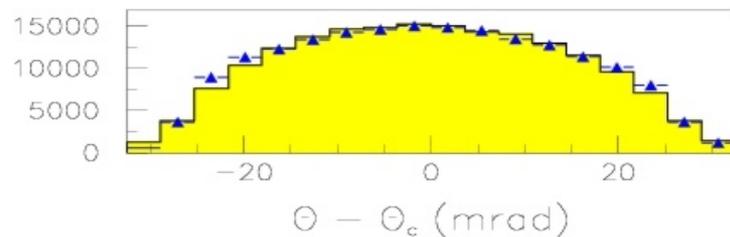

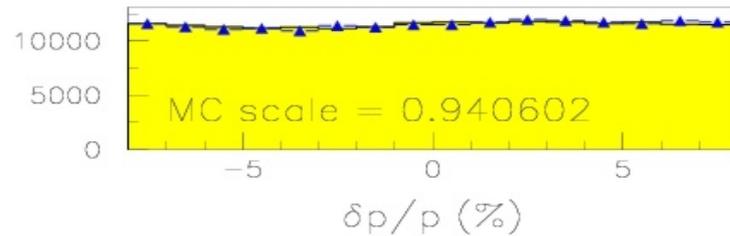

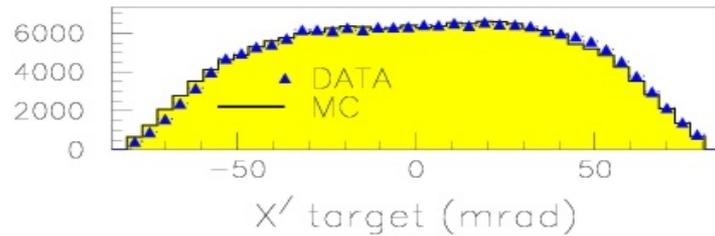

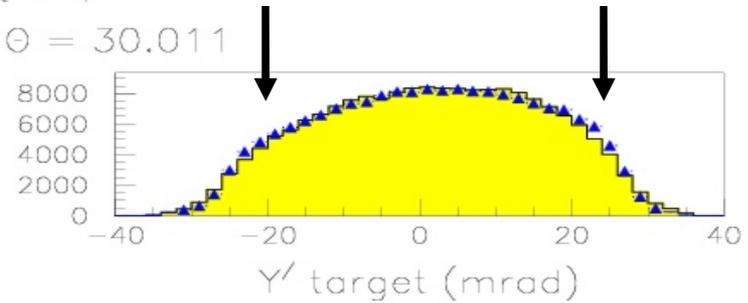

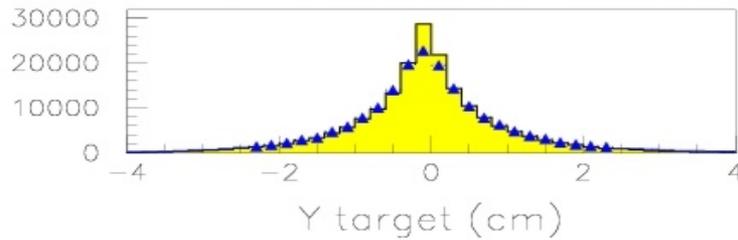

$\delta p/p$  (%) (Ratio Data/MC)

# After Focal Plane Cuts

Run = 53320, Target = 4

$E = 2.3476$ ,  $E' = 0.5137$ ,  $\theta = 30.011$

# Conclusions

→ Fitted MEs at Edges in FP distributions are ***not*** well constrained and are subject to over fitting.

→ events at very edges can only populate This region by multiple scattering, which renders ME fitting unreliable!

- ◆ Need Reliable way to deal with data at edges.
- ◆ Cuts on FP distributions not accurate enough for precision cross sections (diff. in MC forward transport).

# Preferable to improve data MEs over applying FP Cuts

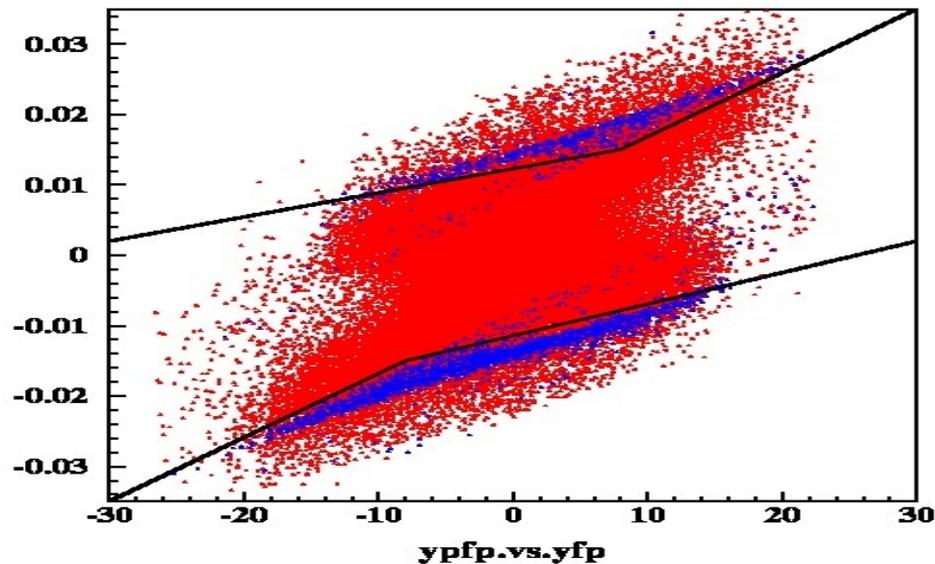

→ Can use fitted MEs in FP region which is well constrained  
(away from edges)

*And*

→ Use COSY in less well constrained region of FP

# Applying Alternate MEs

→ After large combination of possible FP regions studied,  
Decided on looser region to apply alternate (COSY) MEs.  
(HU Ph.D. Student Ya. Li)

Events in central region

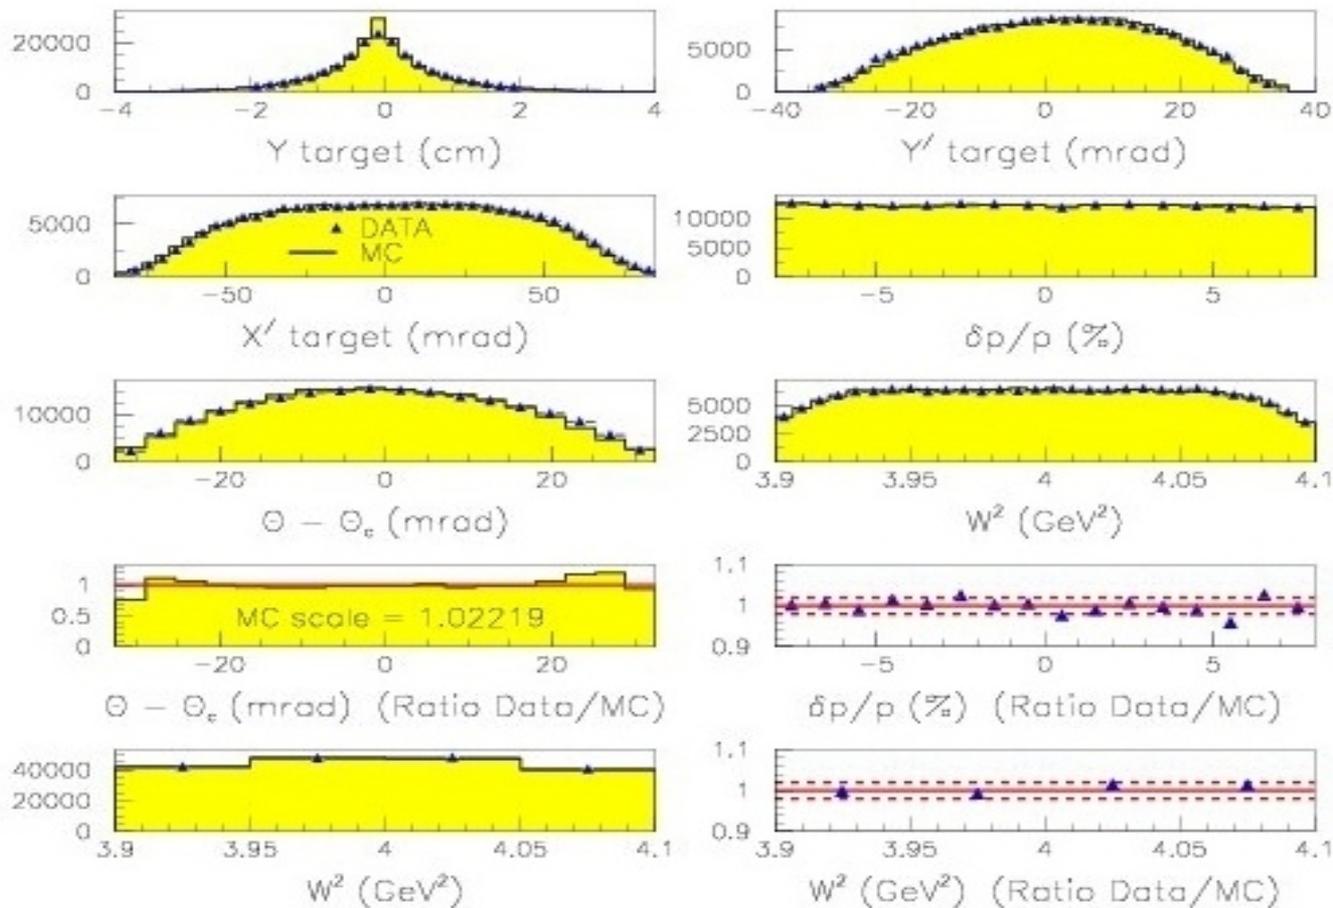

=> apply fitted MEs

Events outside of lines

=> apply COSY MEs.

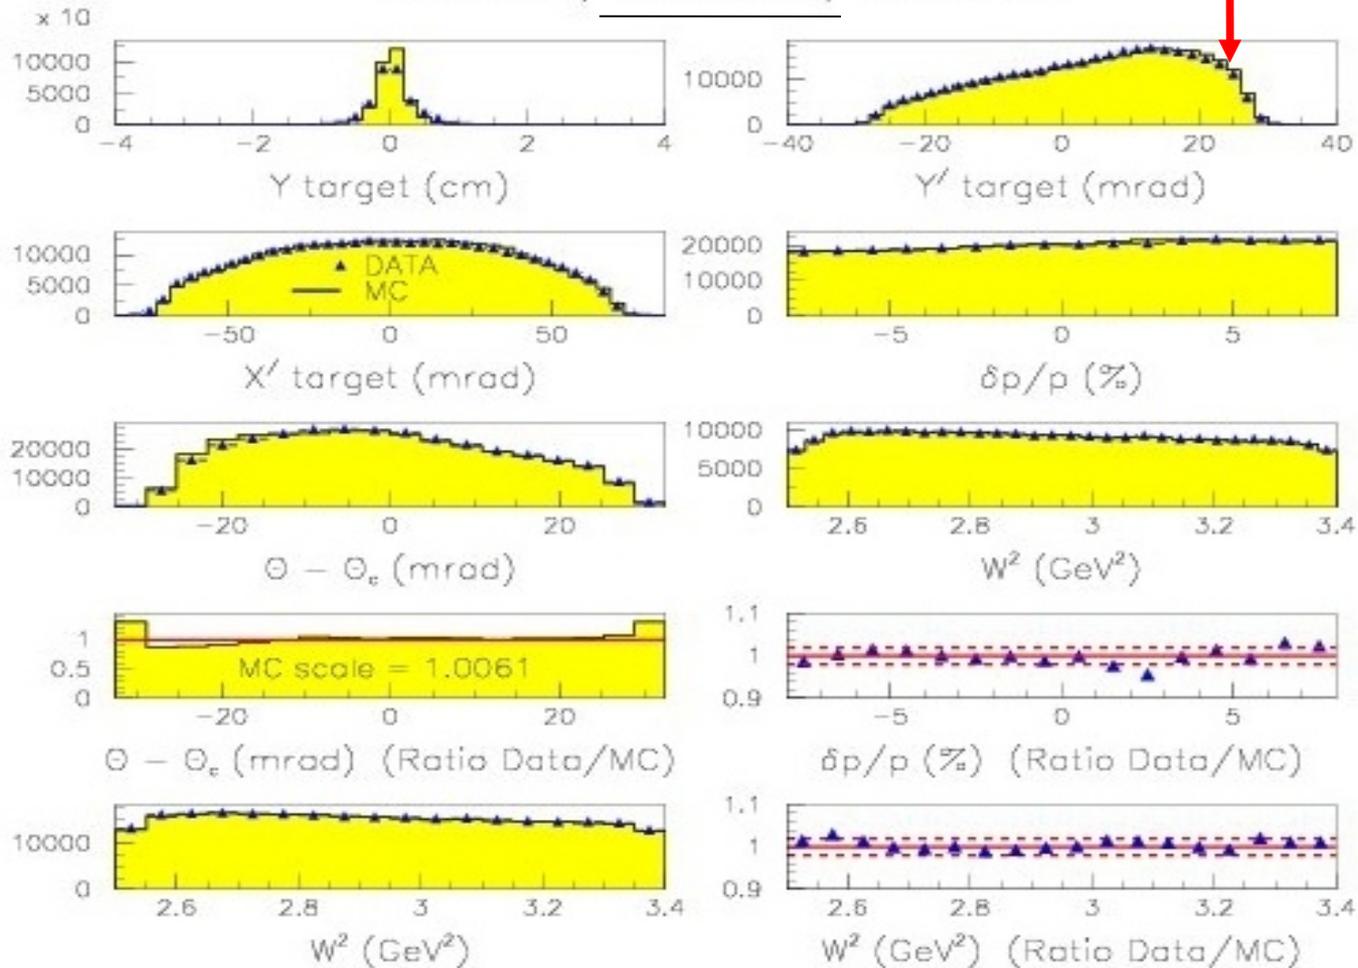

# Alternate ME Results

Run = 53320, Target = 4  
 $E = 2.3476$ ,  $E' = 0.5137$ ,  $\theta = 30.011$

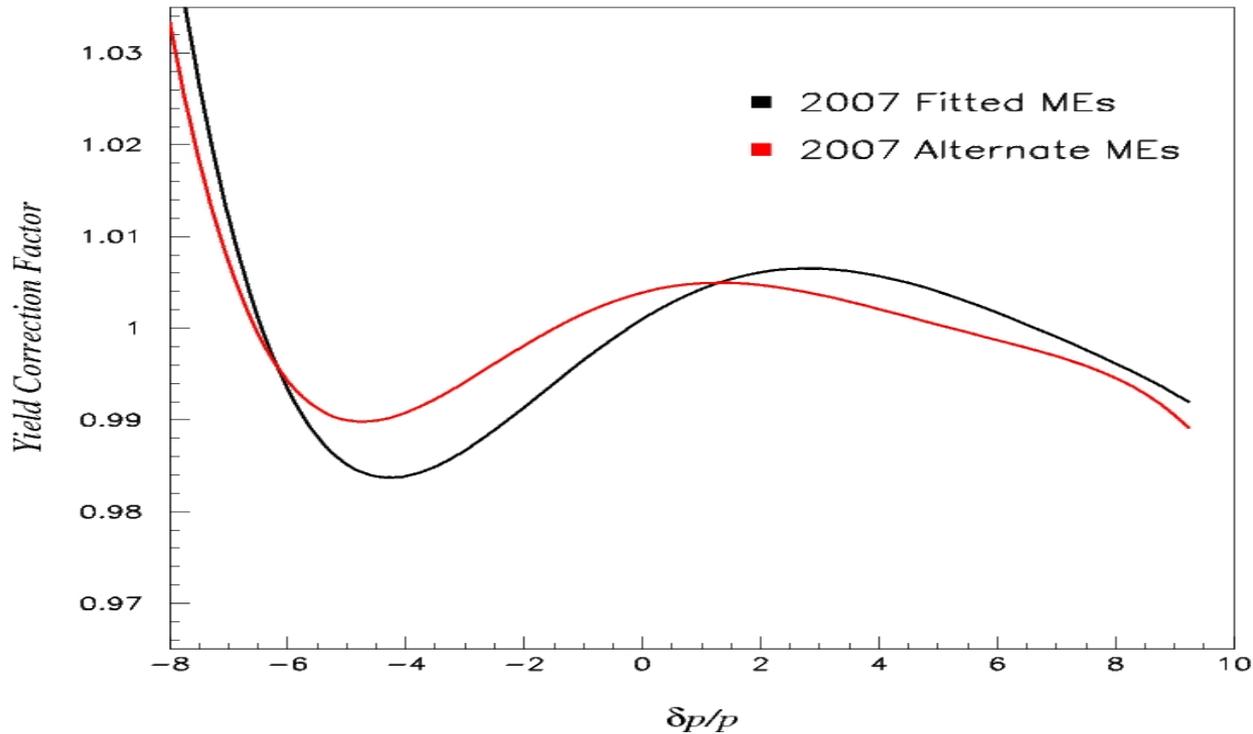

Also improved at high E'

Run = 52599, Target = 4  
 $E = 4.6286$ ,  $E' = 3.2439$ ,  $\theta = 10.671$

# After alternate MEs

- $\delta$  optics correction is reduced with alternate MEs.
- Possible explanation is that over fitting is worse near edge of distributions at FP.

# Conclusions

- Would like to include Alternate Mes in standard Replay Engine.
- Include flag in options file to turn off and on.
- Possibly further optimize FP region of application
