# Determining the Beam Energy 

(Miha Mihovilovic: miham@jlab.org) (15.7.2008)

## Determining the beam energy from the EPICS information:

## Image-1:

The mean energy for Kinematics \#2 : <Eb $>=360.623 \mathrm{MeV} \pm 6.3 \mathrm{E}-3 \mathrm{MeV}$
The mean energy for Kinematics \#11: <Eb $>=361.06 \mathrm{MeV} \pm 4.5 \mathrm{E}-3 \mathrm{MeV}$

## Calculation of Energy Losses:

$$
\begin{aligned}
& \frac{-d E}{d x}=K \frac{Z}{A} \rho \frac{1}{\beta^{2}}\left[\ln \left(\tau^{2}(\tau+2) /\left(2\left(I / m c^{2}\right)^{2}\right)\right)+\left(1-\beta^{2}\right)+\left(\frac{\tau^{2}}{8}-(2 \tau+1) \ln (2)\right) /\left((\tau+1)^{2}\right)-\delta\right] \\
& \delta=2 \ln \left[\frac{28.816}{I} \sqrt{\rho \frac{Z}{A}}\right]+2 \ln \frac{p}{(M c)}-1 \\
& \rho=\frac{p M}{R T}
\end{aligned}
$$

| Element | $\stackrel{\rho}{[\mathrm{g} / \mathrm{cm} 3]}$ | q [g/cm2] | d [cm] | $\begin{gathered} \text { E0 } \\ {[\mathrm{MeV}]} \end{gathered}$ | A | Z | $\Delta E[k e V]$ <br> (without ©) | $\begin{aligned} & \Delta E[k e V] \\ & \text { (with } \delta \text { ) } \end{aligned}$ |

## Fitting Momentum Spectra

(Kinematics \#2)

## Fitting formula that I have used (from Happex):

$$
f\left(E^{\prime}\right)=\sqrt{\frac{\pi}{2}} \frac{\sigma}{\alpha} \exp \left(\frac{1}{2 \alpha}\left(\sigma^{2} / \alpha+2\left(E^{\prime}-b\right)\right)\right) \operatorname{Erfc}\left(\frac{|\alpha|}{\sqrt{2} \sigma \alpha}\left(\sigma^{2} / \alpha+\left(E^{\prime}-b\right)\right)\right)+\frac{c_{1}}{1+\exp \left(\left(E^{\prime}-c_{2}\right) c_{3}\right)}
$$

## ABSOLUTE VALUES:

## A fit to these data using the formula :

$$
p_{\text {measured }}=\frac{E_{0}}{1+\frac{E_{0}}{M}(1-\cos \theta)}
$$

Although the fit looks great, the values of parameters EO and and $\boldsymbol{\theta}$ are incorrect ( Total disagreement with Tiefenbach or nonsensical values depending on the initial values of the fit parameters. For example: The angle theta is off for more than 1 deg ).

## RELATIVE VALUES

First I was trying to determine the momentum scale in both HRS spectrometers. To do this I have used three well known peaks in 12C runs:

Image-6:

Image-7:

## Image-8:

12C - Elastic (\#3092 \& \#3093)

## Image-9:

## Calculated central momentum of the HRSL:

Image-10:

Calculated central momentum of the HRSR:

## Image-11:

$<$ Pcentral $>=k=0.357648 \pm 0.012279 \mathrm{GeV}$ (Not Good !!!)

## Energy differences between various elements and Ta:

Due to big errors we can fit almost anything to these points although this is not obvious until you try it.

## Another approach

To keep the relative error small it is better to fit total energies not differences between them.

Assuming that the uncertainty $\Delta \mathrm{p} 0$ in the HRS central momentum is $<$ few MeV we can use:

$$
\begin{gathered}
E^{\prime}=p_{\text {central }}(1+\delta)=p_{0}\left(1+\frac{\Delta p_{0}}{p_{0}}\right)(1+\delta)=p_{0}(1+\delta)+\Delta p_{0}+\Delta p_{0} \delta \approx p_{0}+\delta p_{0} \\
+\Delta p_{0}+(\text { Something }<0.01 \mathrm{MeV})
\end{gathered}
$$

Then we can use the function:

$$
p_{\text {measured }}=-\Delta p_{0}+\frac{E_{0}}{1+\frac{E_{0}}{M}(1-\cos \theta)}
$$

to directly fit our primary data.
This fit is very UNSTABLE. Because the minimum of the $\mathrm{Chi}^{\wedge} 2$ function is very broad it is very hard to find the correct minimum. There are many combinations (E0, $\theta, \Delta \mathrm{p} 0$ ) that give a good fit to our data. However the values of these parameters are wrong.

We are still looking for the right approach to find a good fit. Any Ideas?
I am currently trying to:

- add a set of additional conditions that will constrain my fit a bit more
- add additional data points (excited 12C and Ta states).
- Bayesian analysis (if it turns out to be promising).
