

# Studying neutron structure at Jefferson Lab through electron scattering off the deuteron, using CLAS12 and the Central Neutron Detector

Paul Naidoo\*, Daria Sokhan\*, Pierre Chatagnon<sup>†</sup>, Silvia Niccolai<sup>†</sup> and Katheryne Price<sup>†</sup> \* University of Glasgow, United Kingdom † IPN Orsay, France

### Generalised Parton Distributions (GPDs)

- GPDs describe spatial and momentum distributions of partons inside hadrons.
  - Relate longitudinal momentum fraction of particles to their transverse position.
  - Provide information on the composition of nucleon spin, and mechanical properties such as pressure.
  - Enable 3D tomography of the nucleon.
- Interactions, under certain kinematic constraints, can be factorised into "hard" QED part and "soft" non-perturbative part which describes internal quark-gluon dynamics.
- Soft part defined by GPDs which depend on:
  - x: longitudinal momentum fraction of the interacting parton.

## CLAS12 Experiment

- Jefferson Laboratory in Virginia Continuous Electron Beam Accelerator Facility.
- CEBAF Large Acceptance Spectrometer 11 GeV beam energy.
- A sophisticated detector suite including micromegas, scintillators, calorimeters, drift chambers and Cherenkov detectors.
- Research varying from studies of hadron structure, hadron spectroscopy, exotic hadrons and beyond.

- $\xi$ : the skewness parameter.
- *t*: squared four-momentum transferred to the target nucleon.
- Extracted via measurements of exclusive processes:
  - Deeply Virtual Compton Scattering
  - Deeply Virtual Meson Production.
- Accurate measurements on both proton and neutron targets would allow for flavour separation of GPDs:

Figure 1: "Handbag" diagrams of DVCS (left) and DVMP (right) [1].

Figure 2: CLAS12 detector schematic.

### Central Neutron Detector (CND)

 Until recently, largest body of work on measurements for GPD extraction has been with proton targets.

### **Reconstruction and PID**

• Neutron detection relies upon strong-interactions with a proton in the scintillator paddles.

## Preliminary CND performance

- Spatial reconstruction accurate
  - Reconstructed position of charged reference particles

- No free neutron target (must use deuterium).
- Neutron cross-section smaller than proton cross-section.
- Detection efficiency of neutrons is low.
- CND included in CLAS12 detector suite for the purpose of taking measurements on deuteron-target neutron-DVCS and DVMP [2].
- CND positioned just inside the central detector solenoid, forming the outer-most layer of the central detectors. Kinematically, n-DVCS neutrons ejected at large angles.
- Design:
- Scintillating barrel detector.
- Made up of 3 layers containing 24 sectors.
- Each sector contains two paddles which are paired via a semicircular light-guide in the downstream direction.
- Each paddle connected to a long light guide leading to Photo-Multiplier Tubes for read out in the upstream direction.

- Ejected proton causes scintillation within paddles.
- Neutron efficiency  $\sim 10\%$ .

- Scintillation light propagates in both directions giving signals in both PMTs.
- The signals are digitised into channels by an ADC. Integral of the ADC represents energy deposited in the scintillator.
- High-resolution timing information extracted from signals using Constant Fraction Discriminators and TDCs.
- Difference in time between paddles used to back-trace to the location of hit in the CND, while their average time is used to calculate the time of hit.

$$z = \frac{1}{2} \cdot v_{eff} \cdot (t_{left} - t_{right}) \qquad t \propto \frac{(t_{left} + t_{right})}{2}$$

- $\beta$  is calculated from time of flight.
- Neutral particles identified by a lack of track in

- compared to CVT track projections.
- Timing resolution close to design goal of  $\sim$  150ps.
- Good resolution of charged and neutral particles.

Figure 7: Plot of  $\beta$  vs.hit-energy for neutral particles.

- Current challenges:
- CVT reconstruction efficiency of protons is currently lower than expected.

Figure 3: Schematic view of CND showing an open cross-section through the solenoid [2].

Central Vertex Tracker (CVT) when a hit occurs in the CND.

- CVT includes Silicon Vertex Tracker and Micromegas.
- Neutrons separated from photons via a cut on  $\beta$ .
- Therefore, protons without tracks are currently polluting neutron signal.
- Work currently underway to determine means of vetoing protons from the neutron signal relying only on the CND and the Central Time of Flight detector, which is a single-layer scintillating barrel detector.)
