Finding the Charge In the Pion

The strong "nuclear" force is believed to be mediated by the exchange of gluons between quarks, neutrons and nuclei, which in turn account for nearly all the visible matter in the universe. The "strong" properties, and it is important to find relatively simple systems for which experiments can provide insight. The pion is the lightest known strongly interacting particle, with about one seventh the mass of a nucleon, such as its precise mass, its lifetime (less than one microsecond), and the spatial distribution of its charge. These clues about the nature of the strong force.

The pion is often pictured as built from one each of the lightest quarks and anti-quarks; in fact, quantum chromodynamics predicts that it exhibits precisely this structure in the limit of very-high-energy scattering experiments. At lower energies, these two tiny contributors, but instead from a "sea" of additional quark-antiquark pairs, along with gluons, making it more complex at lower energies. One important question is to determine the energy region where the simple quark-antiquark picture emerges.

Recently, determination of the pion's charge distribution has been pushed to the highest possible precision and the shortest distance scales previously accessible with modern techniques. A charge distribution is measured by observing the pattern of electrons that scatter from the desired object that is placed in front of an intense electron beam. Since pions have such a short lifetime, the experiment uses a container of hydrogen, whose nuclei (each consisting of a single proton) are continuously surrounded by a "cloud" of pions which in turn serve as the "target" for the beam.

The new results from this experiment indicate that the short-distance scale studied in this experiment is still far from the region where the simple quark-antiquark picture of the pion emerges, but the information is still useful for understanding the more complex contributions from gluons and the quark-antiquark "sea." Plans are now underway to push these measurements closer to the transition region with the planned energy upgrade at Jefferson Lab.

The experiment was carried out at the **Department of Energy's Jefferson Lab in Newport News, Virginia, by an international collaboration including groups from Canada and the Netherlands, as well as several groups supported by the NSF Nuclear Physics Program, including the University of Maryland, Hampton University, James Madison University, the College of William and Mary, and California State University - Los Angeles. The experiment constituted the Ph.D. thesis of NSF-supported graduate student Tanja Horn from the University of Maryland.**

Primary Strategic Outcome Goal:

Discovery: Foster research that will advance the frontiers of knowledge, emphasizing areas of greatest opportunity and potential benefit and establishing the nation as a global leader in fundamental and transformational science and engineering.

Secondary Strategic Outcome Goals:

Learning: Cultivate a world-class, broadly inclusive science and engineering workforce, and expand the scientific literacy of all citizens.

Researchers Observe Rare Light-emitting Decay of Neutrons

Neutrons -- the tiny particles that match with protons to form the innards of nearly every atom in the universe -- decay when they are outside an atomic nucleus. For decades, researchers have predicted but never proved that roughly 1 in 1,000 of those decays take the form of an energetic photon.

Now, for the first time, researchers have caught the photons from that "radiative decay" in action. Reporting in the Dec. 22 issue of *Physical Review Letters*, a team of researchers from the United States and Britain show results that may confirm neutron radiative decay.

The research was conducted by physicists at Tulane University, University of Michigan and University of Maryland (all supported by NSF) in collaboration with scientists at the National Institute of Standards and Technology Physics Laboratory and the University of Sussex in the United Kingdom.

Andy Rogers, doctoral student at the [Michigan State University National Superconducting Cyclotron Laboratory \(NSCL\)](#), adjusts a detector that measures charge, mass and other properties of nuclear fragments. NSCL helps to train 10% of the nation's nuclear physics PhDs.

Jill Pinter, doctoral student at the [Michigan State University National Superconducting Cyclotron Laboratory \(NSCL\)](#), works on the apparatus that measures magnetic properties of short-lived nuclei. NSCL is the nation's largest university campus-based nuclear physics laboratory.

Chris Compton, research engineer at the [Michigan State University National Superconducting Cyclotron Laboratory \(NSCL\)](#), inspects prototype prototype superconducting radio frequency cavities. NSCL is making strategic investments in next-generation accelerator technology.

Through its participation in the [Joint Institute for Nuclear Astrophysics \(JINA\)](#), the [Michigan State University National Superconducting Cyclotron Cyclotron Laboratory](#) fosters interdisciplinary work in nuclear astrophysics, astrophysics, including research on how elements are created in stellar explosions.

HARDY

An NSF-supported community outreach program encourages students in communities surrounding the [Michigan State University National Superconducting Cyclotron Laboratory \(NSCL\)](#) to create science-inspired art – some of which is on display in the NSCL lobby.

NSF and DUSEL

- Well-matched to NSF mission:
 - Broad, multidisciplinary scientific program
 - New & unique opportunities for growth, diversity, interdisciplinary research
 - Intrinsically strong program for education, outreach
- DUSEL is a joint initiative within NSF between **Physics (lead), Engineering, and Geosciences**
 - Biology currently serving in advisory capacity
- Will enable new, long-term partnerships between disciplines, organizations - public, private, international

Searching for New Forces with the Electron's Weak Charge

Cartoon representing how two electrons will interact by the exchange of particles. The two known forces of electromagnetism and the weak force are described by the exchange of a photon and a Z boson, respectively. This experiment searched for the exchange of possible new particles, which would represent a new force.

The **Physics Frontiers Centers (PFC)** program supports university-based centers and institutes where the collective efforts of a larger group of individuals can enable transformational advances in the most promising research areas. The program is designed to foster major breakthroughs at the intellectual frontiers of physics by providing needed resources such as combinations of talents, skills, disciplines, and/or specialized infrastructure, not usually available to individual investigators or small groups, in an environment in which the collective efforts of the larger group can be shown to be seminal to promoting significant progress in the science and the education of students. Activities supported through the program are in all sub-fields of physics within the purview of the Division of Physics: atomic, molecular, optical, plasma, elementary particle, nuclear, astro-, gravitational, and biological physics. Interdisciplinary projects at the interface between these physics areas and other disciplines and physics sub-fields, e.g. biology, quantum information science, mathematical physics, condensed matter physics, and emerging areas of physics are also included.

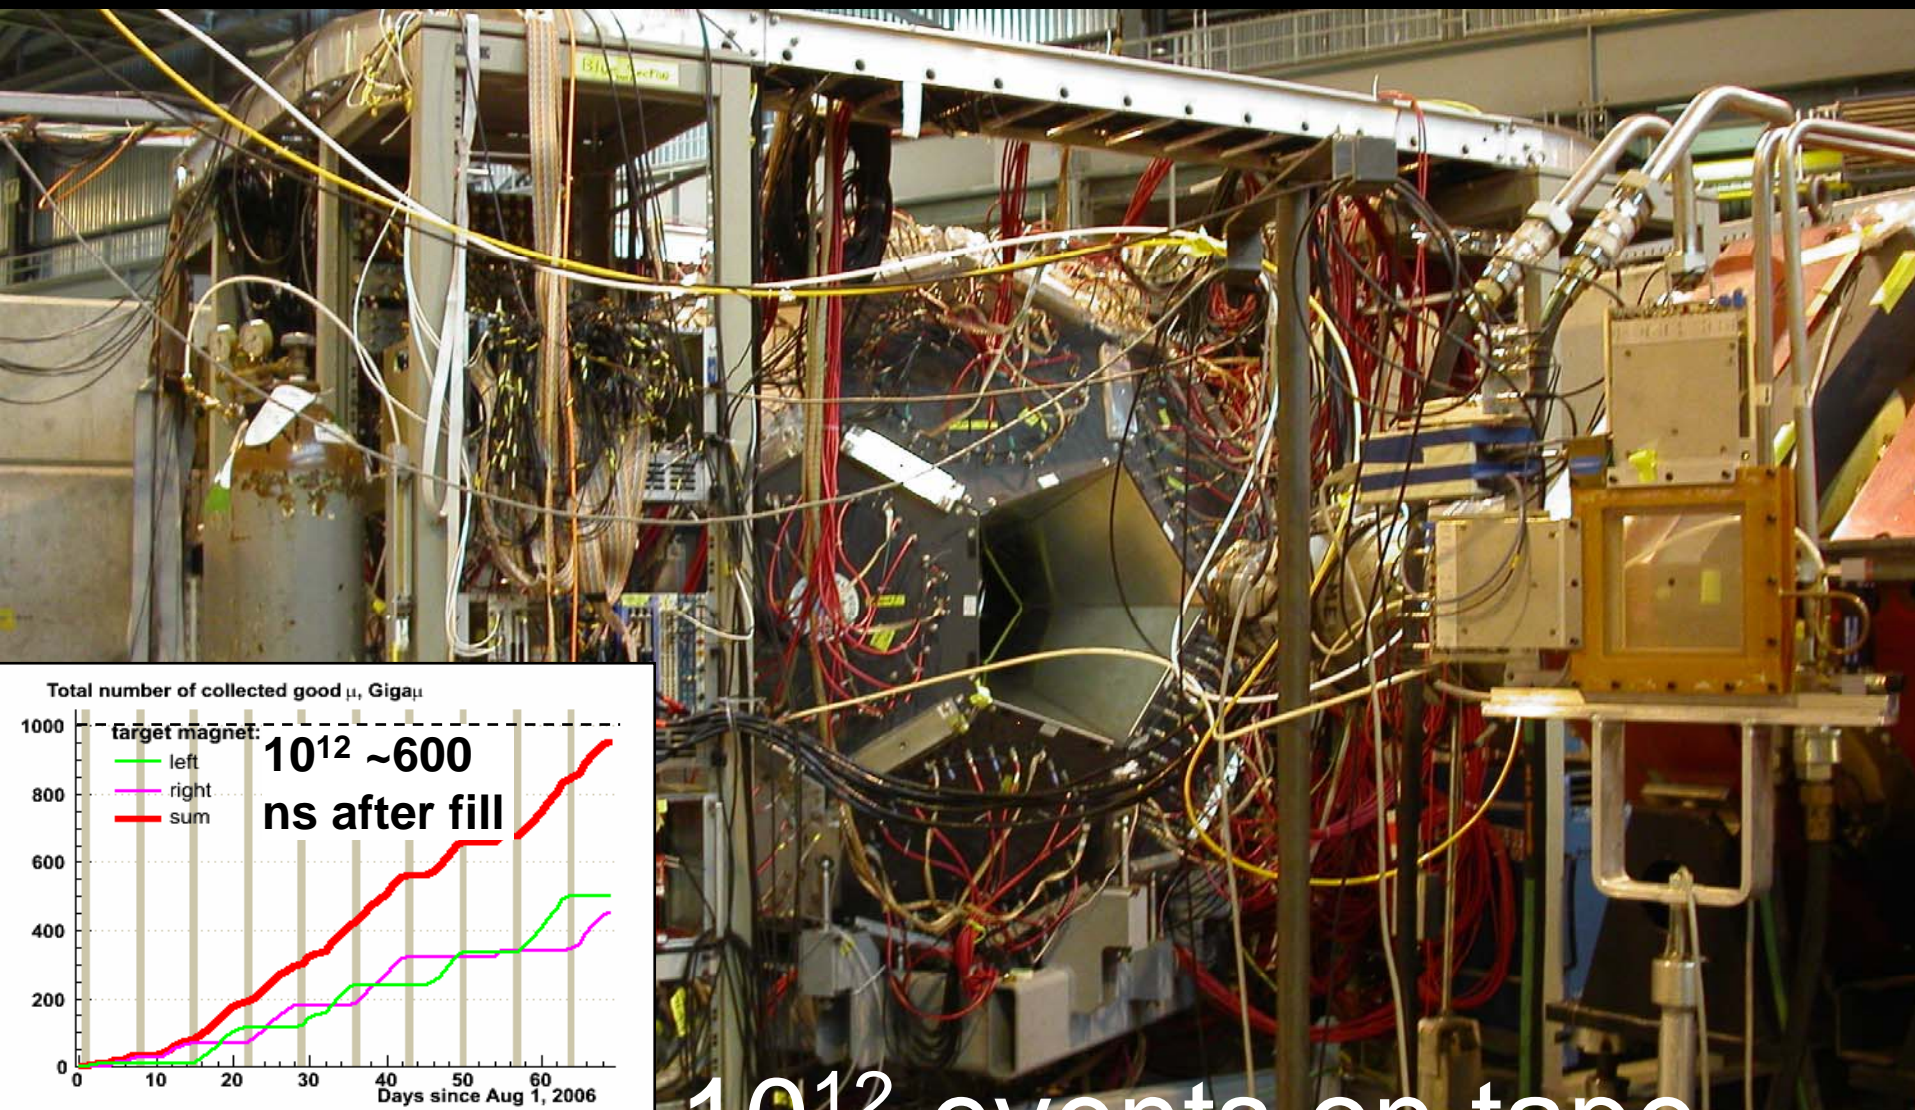

The Bigger Picture...

- Construction funds for projects of this size & scope are developed through the Major Research Equipment and Facilities Construction (MREFC) line at NSF
- MREFC projects are funded via separate congressional budget line items (New money)
- Construction start requires approval from the National Science Board (NSB) and, ultimately, Congress
- Additionally, projects must pass a readiness threshold (Preliminary Design Stage) before they can move forward to the NSB for consideration
