Summary

- Original Feynman approach to PDFs  $f(x)$ : infinite momentum  $P_3 \rightarrow \infty$  limit of  $k_3 = xP_3$  momentum distributions ( $\sim$  quasi-PDFs  $Q(x, P_3)$ )
- $f(x)$  were treated as  $k_\perp$ -integrated  $f(x, k_\perp)$  distributions
- Understood from the start:  $Q(x, P_3 \rightarrow \infty) \rightarrow f(x)$  limit exists only if  $f(x, k_\perp)$  rapidly decreases with  $k_\perp$
- “Transverse momentum cut-off”,  $\langle k_\perp^2 \rangle \sim 1/R_{\text{hadr}}^2$
- Question 1: why  $Q(x, P_3)$  differs from  $f(x)$ ?
- Question 2: how does  $Q(x, P_3)$  convert into  $f(x)$  when  $P_3 \rightarrow \infty$ ?
- Qualitative answer:  $yP_3$  comes from two sources:  
from the motion of the hadron ( $xP_3$ ) and  
from Fermi motion of quarks inside the hadron ( $(y-x)P_3 \sim 1/R_{\text{hadr}}$ )

- $(y-x)P_3 \sim 1/R_{\text{hadr}}$  part has the same origin as transverse momentum
- $\Rightarrow$  One should be able to relate quasi-PDFs to TMDs

Results

Summary

- Basic matrix element (ignoring spin)

$$\langle p | \phi(0) \phi(z) | p \rangle = \mathcal{M}(-pz, -z^2)$$

- Lorentz invariance:  $\mathcal{M}$  depends on  $z$  through  $(pz)$  and  $z^2$

- Take  $z = (0, 0, 0, z_3)$ , then  $-(pz) \equiv \nu = Pz_3$  and  $-z^2 = z_3^2$
- loffe time  $\nu$ :  $\mathcal{M}(\nu, z_3^2) =$  loffe time pseudo-distribution (pseudo-ITD)
- Introduce quasi-PDF (Ji,2013)

$$Q(y, P) = \frac{P}{2\pi} \int_{-\infty}^{\infty} dz_3 e^{-iyPz_3} \mathcal{M}(Pz_3, z_3^2) = \int_{-\infty}^{\infty} \frac{d\nu}{2\pi} e^{-iy\nu} \mathcal{M}(\nu, \nu^2/P^2)$$

- Take  $z = (z_+ = 0, z_-, z_1, z_2)$ , then  $\nu = -p^+ z^-$  and  $-z^2 = z_1^2 + z_2^2$ . TMD:

$$\mathcal{M}(\nu, z_1^2 + z_2^2) = \int_{-1}^1 dx e^{ix\nu} \int_{-\infty}^{\infty} dk_1 dk_2 e^{i(k_1 z_1 + k_2 z_2)} \mathcal{F}(x, k_1^2 + k_2^2)$$

- Take  $z_1 = 0, z_2 = \nu/P$  and use for qPDF

$$Q(y, P) = P \int_{-1}^1 dx \int_{-\infty}^{\infty} dk_1 \mathcal{F}(x, k_1^2 + (y-x)^2 P^2)$$

- qPDF variable  $y$  has the  $-\infty < y < \infty$  support, since  $-\infty < k_2 < \infty$

Results

### Summary

- **Pseudo-PDF**  $\mathcal{P}(x, -z^2)$ : Fourier transform of pseudo-ITD with respect to  $\nu$

$$\mathcal{M}(\nu, -z^2) = \int_{-1}^1 dx e^{-ix\nu} \mathcal{P}(x, -z^2)$$

- Limits  $-1 \leq x \leq 1$  for any Feynman diagram. Relation to TMD

$$\mathcal{P}(x, z_{\perp}^2) = \int d^2\mathbf{k}_{\perp} e^{i(\mathbf{k}_{\perp} \mathbf{z}_{\perp})} \mathcal{F}(x, k_{\perp}^2)$$

- When  $\mathcal{F}(x, k_{\perp}^2)$  rapidly vanishes with  $k_{\perp}$ , pseudo-PDF and pseudo-ITD are regular for  $z^2 = 0$ , and  $\mathcal{P}(x, 0) = f(x)$
- Quasi-PDF to pseudo-PDF relation

$$Q(y, P) = \frac{|P|}{2\pi} \int_{-1}^1 dx \int_{-\infty}^{\infty} dz_3 e^{-i(y-x)Pz_3} \mathcal{P}(x, z_3^2)$$

- Expand  $\mathcal{P}(x, z_3^2)$  in  $z_3^2$

$$\mathcal{P}(x, z_3^2) = \sum_{l=0}^{\infty} (z_3^2 \Lambda^2)^l \mathcal{P}_l(x)$$

- $Q(y, P)$  approaches  $f(y)$  like

$$Q(y, P) = f(y) + \sum_{l=1}^{\infty} \left( \frac{\Lambda^2}{P^2} \right)^l \frac{\partial^{2l}}{\partial y^{2l}} \mathcal{P}_l(y)$$

### Evolution in lattice data

Data

Building  $\overline{MS}$  ITD

Results

### Summary

$$Q(y, P) = f(y) + \sum_{l=1}^{\infty} \left( \frac{\Lambda^2}{P^2} \right)^l \frac{\partial^{2l}}{\partial y^{2l}} \mathcal{P}_l(y)$$

- Support mismatch:  $-\infty < y < \infty$  for qPDF  $Q(y, P)$ , while  $\mathcal{P}_l(y)$ 's vanish outside  $-1 \leq y \leq 1$
- Do not take this expansion too literally
- Innocently-looking derivatives of  $\mathcal{P}_l(y)$  generate infinite tower of singular functions like  $\delta(y)$ ,  $\delta(y \pm 1)$  and their derivatives
- Recall: even if a function  $f(y)$  has a nontrivial support  $\Omega$  (say,  $-1 \leq y \leq 1$ ), one may formally represent it by a series

$$f(y) = \sum_{N=0}^{\infty} \frac{(-1)^N}{N!} M_N \delta^{(N)}(y)$$

over the functions  $\delta^{(N)}(y)$  with an apparent support at one point  $y = 0$  only

- $M_N$  are moments of  $f(y)$

$$M_N = \int_{\Omega} dy y^N f(y)$$

- While the difference between  $Q(y, P)$  and  $f(y)$  is formally given by a series in powers of  $1/P^2$ , its coefficients are not the ordinary functions of  $y$

### Evolution in lattice data

Data

Building  $\overline{MS}$  ITD

Results

### Summary

- In terms of TMDs:

$$Q(y, P) = f(y) + \sum_{l=1}^{\infty} \int d^2 k_{\perp} \frac{k_{\perp}^{2l}}{4^l P^{2l} (l!)^2} \frac{\partial^{2l}}{\partial y^{2l}} \mathcal{F}(y, k_{\perp}^2)$$

- To eliminate mismatch, take  $y^n$  moments  $\langle y^n \rangle_Q$  of the quasi-PDFs

$$\langle y^n \rangle_Q \equiv \int_{-\infty}^{\infty} dy y^n Q(y, P) = \sum_{l=0}^{[n/2]} \frac{n!}{(n-2l)!(l!)^2} \frac{\langle x^{n-2l} k_{\perp}^{2l} \rangle_{\mathcal{F}}}{4^l P^{2l}}$$

- $\langle x^{n-2l} k_{\perp}^{2l} \rangle_{\mathcal{F}}$  are the combined moments of TMDs

$$\langle x^{n-2l} k_{\perp}^{2l} \rangle_{\mathcal{F}} \equiv \int_{-1}^1 dx x^{n-2l} \int d^2 k_{\perp} k_{\perp}^{2l} \mathcal{F}(x, k_{\perp}^2)$$

- Expansion makes sense only when  $\mathcal{F}(x, k_{\perp}^2)$  vanishes faster than any power of  $1/k_{\perp}^2$
- Is it possible to study the approach of  $Q(y, P)$  to  $f(y)$  for fixed  $y$ ?

### Evolution in lattice data

Data

Building  $\overline{MS}$  ITD

Results

### Summary

- $z_3$ -dependence has the same origin as  $k_{\perp}$  dependence of TMDs
- Quasi-PDFs can be obtained from TMDs (A.R., 2016)

$$Q(y, P)/P = \int_{-1}^1 dx \int_{-\infty}^{\infty} dk_1 \mathcal{F}(x, k_1^2 + (y-x)^2 P^2)$$

- Or from pseudo-PDFs

$$Q(y, P) = \frac{P}{2\pi} \int_{-1}^1 dx \int_{-\infty}^{\infty} dz_3 e^{i(x-y)(Pz_3)} \mathcal{P}(x, z_3^2)$$

- Try factorized model

$$\mathcal{P}(x, z_3^2) = f(x)I(z_3^2)$$

- Popular idea: Gaussian dependence  $I(z_3^2) = e^{-z_3^2 \Lambda^2/4}$

$$Q_G^{\text{fact}}(y, P) = \frac{P}{\Lambda\sqrt{\pi}} \int_{-1}^1 dx f(x) e^{-(y-x)P^2/\Lambda^2}$$

### Summary

- Take PDF  $f(x) = u_v(x) - d_v(x) = \frac{315}{32} \sqrt{x}(1-x)^3 \theta(0 \leq x \leq 1)$  obtained by pseudo-PDF method (Orginos et al. 2017)

- Curves for  $P/\Lambda = 0.75, 1.5, 2.25$  are close to qPDFs obtained by Lin et al (2016), upper momentum  $P = 1.3$  GeV, effective  $\Lambda \approx 600$  MeV
- Need  $P \sim 4.5 \Lambda \approx 2.7$  GeV to get reasonably close to input PDF
- Note a lot of dirt for negative  $y$ , even for  $P/\Lambda = 4.5$

### Evolution in lattice data

Data

Building  $\overline{MS}$  ITD

Results

### Summary

- How do the quasi-PDF curves approach the limiting PDF curve point by point in  $y$ ?
- Take a simple input PDF  $f(x) = 1 - x$  (and Gaussian dependence on  $k_{\perp}$ )

Analytic form:

$$Q(y, P) = \frac{1}{2}(1 - y) \left[ \operatorname{erf} \left[ (1 - y)P/\Lambda \right] + \operatorname{erf} \left[ yP/\Lambda \right] \right] + \frac{\Lambda}{2\sqrt{\pi}P} \left[ e^{-(1-y)^2 P^2/\Lambda^2} - e^{-y^2 P^2/\Lambda^2} \right]$$

- $P$ -dependence reflects the  $k_{\perp}$ -dependence of TMD
- In the middle of the  $0 \leq y \leq 1$  interval

$$Q(1/2, P) = \frac{1}{2} - \frac{\Lambda e^{-P^2/4\Lambda^2}}{\sqrt{\pi}P} \left[ 1 - \frac{2\Lambda^2}{P^2} - \dots \right]$$

- The approach to the limiting value is  $\sim e^{-P^2/4\Lambda^2}$  rather than a powerlike
- For  $y = 1$ , the approach is like  $\sqrt{\Lambda^2/P^2}$

$$Q(1, P) = \frac{\Lambda}{2\sqrt{\pi}P} \left[ 1 - e^{-P^2/\Lambda^2} \right]$$

rather than like  $\Lambda^2/P^2$

Non-analytic behavior with respect to  $\Lambda^2/P^2$  is present at another end-point as well

$$Q(0, P) = \frac{1}{2} + \frac{\Lambda}{2\sqrt{\pi}P} \left[ 1 - 2e^{-P^2/\Lambda^2} \left( 1 - \frac{\Lambda^2}{4P^2} - \dots \right) \right]$$

- Quasi-PDF approaches 1/2, average of its  $0_+$  and  $0_-$  limits of the input PDF

- Curves illustrating  $P$ -dependence of quasi-PDFs for particular values of  $y$
- With just three points, at  $P/\Lambda = 0.75, 1.5$  and  $2.25$ , it is rather difficult to make an accurate extrapolation to correct  $P = \infty$  values

- $k_\perp$  effects generate a very nontrivial TMD-dependent pattern of nonperturbative evolution of the quasi-PDFs  $Q(y, P)$
- It cannot be described by a  $\mathcal{O}(\Lambda^2/P^2)$  correction on the point-by-point basis in  $y$ -variable

Results

Summary

- All  $(\Lambda^2/P^2)^n$  corrections come from  $\langle k_{\perp}^{2n} \rangle_{\mathcal{F}}$  moments of TMD  $F(x, k_{\perp}^2)$
- Statement is based on the ordinary Taylor expansion. In scalar case

$$\phi(0)\phi(z) = \sum_{n=0}^{\infty} \phi(0)(z\partial)^N \phi(0)$$

- Usual statement:  $(1/P^2)^N$  terms come from higher twists and target mass corrections (TMCs)
- Expand  $(z\partial)^N$  over the combinations  $\{z\partial\}^l$  involving traceless tensor  $\{z_{\mu_1} \dots z_{\mu_n}\}$

$$\{z\partial\}^l \equiv \{z_{\mu_1} \dots z_{\mu_l}\} \partial^{\mu_1} \dots \partial^{\mu_l}$$

- Obtain twist expansion. In scalar case

$$\phi(0)\phi(z) = \sum_{l=0}^{\infty} \left(\frac{z^2}{4}\right)^l \sum_{N=0}^{\infty} \frac{N+1}{l!(N+l+1)!} \phi(0)\{z\partial\}^N (\partial^2)^l \phi(0)$$

- For matrix elements, combination  $\{z\partial\}^N$  translates into

$$\{pz\}^N \equiv z_{\mu_1} \dots z_{\mu_N} \{p^{\mu_1} \dots p^{\mu_N}\}$$

- Take  $n = 2$ . Then  $\{zp\}^2 = (zp)^2 + \frac{1}{4}z^2M^2$
- Transformation to quasi-PDF converts  $z^2$  into  $1/P^2$  which gives  $M^2/P^2$  TMC

Reduced pseudo-ITD

### Evolution in lattice data

Data

Building  $\overline{MS}$  ITD

Results

### Summary

- Evident conclusion: TMCs in qPDFs are created “by hand”
- Apply twist decomposition to simplest matrix element, and define  $\langle p | \phi(0) \partial^2 \phi(0) | p \rangle = \lambda^2 \langle p | \phi(0) \phi(0) | p \rangle$

$$\langle p | \phi(0) (z\partial)^2 \phi(0) | p \rangle = - \left[ (zp)^2 + \frac{1}{4} z^2 M^2 \right] \langle x^2 \rangle_f + \frac{z^2}{4} \lambda^2$$

- Using expression of ME in terms of the TMD

$$\langle p | \phi(0) (z\partial)^2 \phi(0) | p \rangle = - (zp)^2 \langle x^2 \rangle_f + \frac{z^2}{2} \langle k_{\perp}^2 \rangle_{\mathcal{F}}$$

- This gives relation  $M^2 \langle x^2 \rangle_f + \lambda^2 = 2 \langle k_{\perp}^2 \rangle_{\mathcal{F}}$
- In explicit form,

$$\langle p | \phi(0) \partial^2 \phi(0) | p \rangle = -M^2 \int_0^1 dx x^2 f(x) + 2 \int_0^1 dx \int d^2 k_{\perp} k_{\perp}^2 \mathcal{F}(x, k_{\perp}^2)$$

- Simple estimate. Take  $f(x) = 4(1-x)^3$ , then

$$\frac{M^2}{2} \int_0^1 dx x^2 f(x) = \frac{M^2}{30} \approx 0.03 \text{ GeV}^2$$

- More realistic valence PDFs  $f(x)$  are singular for  $x = 0$ , and integral is even smaller. For  $f(x) \sim (1-x)^3 / \sqrt{x}$ , it equals to  $M^2/66 \approx 0.013 \text{ GeV}^2$
- For Gaussian TMD  $\langle k_{\perp}^2 \rangle_G = \Lambda^2 \sim 0.1 \text{ GeV}^2$  for  $\Lambda = 300 \text{ MeV}$
- Target-mass corrections are much smaller than  $k_{\perp}$  effects

## Summary

- In QCD  $\mathcal{F}(x, k_{\perp}^2)$  has  $1/k_{\perp}^2$  hard part and moments  $\langle x^{n-2l} k_{\perp}^{2l} \rangle_{\mathcal{F}}$  diverge
- In the  $l = 0$  case, the divergence is logarithmic
- Reflects the perturbative evolution of quasi-PDFs  $Q(y, P)$  for large  $P$
- Logarithmic singularity in  $z_3^2$  in coordinate representation. At one loop,

$$\mathcal{M}^{\text{hard}}(\nu, z_3^2) = -\frac{\alpha_s}{2\pi} C_F \ln(z_3^2) \int_0^1 du B(u) \mathcal{M}^{\text{soft}}(u\nu, 0)$$

- Altarelli-Parisi (AP) evolution kernel

$$B(u) = \left[ \frac{1+u^2}{1-u} \right]_+$$

- The function  $\mathcal{M}(\nu, \nu^2/P^2)$  that generates the quasi-PDF gets

$$\mathcal{M}^{\text{hard}}(\nu, \nu^2/P^2) = -\frac{\alpha_s}{2\pi} C_F \ln(\nu^2/P^2) \int_0^1 du B(u) \int_{-1}^1 dx e^{-iux\nu} f^{\text{soft}}(x)$$

- Hard part of the quasi-PDF  $Q(y, P)$  has a  $\ln P^2$  term

$$Q^{\text{hard}}(y, P) = \ln(P^2) \Delta(y) + \dots$$

- It is nonzero in the  $-1 \leq y \leq 1$  region only

$$\Delta(y) = \frac{\alpha_s}{2\pi} C_F \int_0^1 \frac{du}{u} B(u) f^{\text{soft}}(y/u)$$

### Evolution in lattice data

Data

Building  $\overline{MS}$  ITD

Results

### Summary

- In  $z_3^2$  singularity of the ITD leads to a logarithmic perturbative evolution of the quasi-PDF  $Q(y, P)$  for large  $P$
- For TMDs, the  $\ln z^2$  behavior translates into large- $k_\perp$  hard tail

$$\mathcal{F}^{\text{hard}}(x, k_\perp^2) = \frac{\Delta(x)}{\pi k_\perp^2}$$

- Regularizing  $1/k_\perp^2 \rightarrow 1/(k_\perp^2 + m^2)$  gives

$$\int_{-\infty}^{\infty} \frac{dk_1}{k_1^2 + (x-y)^2 P^2 + m^2} = \frac{\pi}{\sqrt{(x-y)^2 P^2 + m^2}}$$

- Determines the hard part of a quasi-distribution

$$\begin{aligned} Q^{\text{hard}}(y, P) &= \int_{-1}^1 dx \frac{\Delta(x)}{\sqrt{(x-y)^2 + m^2/P^2}} \\ &= C_F \frac{\alpha_s}{2\pi} \int_{-1}^1 \frac{d\xi}{|\xi|} R(y/\xi, m^2/\xi^2 P^2) f^{\text{soft}}(\xi) \end{aligned}$$

- Generating kernel  $R(\eta, m^2/P^2)$

$$R(\eta; m^2/P^2) = \int_0^1 du \frac{B(u)}{\sqrt{(\eta-u)^2 + m^2/P^2}}$$

Results

### Summary

- Kernel for several values of  $P/m$
- Understand  $m$  as IR cut-off  
 $\sim 1/R_{\text{hadr}} \sim 0.5 \text{ GeV}$
- In the  $m/P \rightarrow 0$  limit

$$\frac{1}{\sqrt{(x-y)^2 + m^2/P^2}} \Big|_{m^2/P^2 \rightarrow 0} = \left( \frac{1}{|x-y|} \right)_+ + \delta(x-y) \ln \left[ 4y(1-y) \frac{P^2}{m^2} \right]$$

- $\delta(x-y)$  gives  $\ln P^2$  evolution in  $-1 \leq y \leq 1$  region
- Outside  $|\eta| \leq 1$  region, limit  $m/P \rightarrow 0$  is finite

$$R(\eta; 0) = \int_0^1 \frac{du}{|\eta - u|} B(u)$$

- Kernel can be written as a series in  $1/\eta$ ,

$$R(\eta; 0)|_{|\eta| > 1} = - \sum_{n=1}^{\infty} \frac{\gamma_n}{\eta^{n+1}} \quad , \quad R(\eta; 0)|_{|\eta| < -1} = \sum_{n=1}^{\infty} \frac{\gamma_n}{\eta^{n+1}}$$

## Pseudo- & Quasi-PDFs

Results

### Summary

$$R(\eta; 0)|_{\eta > 1} = - \sum_{n=1}^{\infty} \frac{\gamma_n}{\eta^{n+1}} \quad , \quad R(\eta; 0)|_{\eta < -1} = \sum_{n=1}^{\infty} \frac{\gamma_n}{\eta^{n+1}}$$

- $\gamma_n$  are proportional to anomalous dimensions of operators with  $n$  derivatives

$$\gamma_n = \int_0^1 du u^n B(u)$$

- $\gamma_0 = 0$ , hence the asymptotic behavior for large  $|\eta|$  is

$$R(\eta; 0)|_{|\eta| \gg 1} = -\frac{4}{3} \frac{\text{sgn}(\eta)}{\eta^2} + \mathcal{O}(1/\eta^3)$$

- Explicit expression for  $m/P = 0$

$$R(\eta; 0)|_{\eta > 1} = \frac{1 + \eta^2}{\eta - 1} \ln \left( \frac{\eta - 1}{\eta} \right) + \frac{3}{2(\eta - 1)} + 1$$

- Realistic value  $P/m \sim 3$
- Curve is very far from asymptotic shape
- Neglecting  $\alpha_s$  correction is a better approximation than using it in the  $m/P = 0$  limit

# Subtlety of $P \rightarrow \infty$ limit

 &= C_F \frac{\alpha_s}{2\pi} \int_{-1}^1 \frac{d\xi}{|\xi|} R(y/\xi, m^2/\xi^2 P^2) f^{\text{soft}}(\xi)
 \end{aligned}$$

- Outside  $|\eta| < 1$ , the kernel has finite  $P \rightarrow \infty$  limit

$$R(\eta; 0)|_{\eta > 1} = \frac{1 + \eta^2}{\eta - 1} \ln \left( \frac{\eta - 1}{\eta} \right) + \frac{3}{2(\eta - 1)} + 1$$

- Even when powers of  $\Lambda^2/P^2$  may be neglected, quasi-PDFs differ from PDFs
- Shape of  $Q(y, P)$  for  $y > 1$  is calculable (if PDF is known)
- One should see that lattice gives it, and subtract
- Only then one gets PDF with  $|x| \leq 1$  support

Results

### Summary

- Terms outside  $|y| \leq 1$  are generated by  $\ln z_3^2$  term
- In QCD, there is one more source of the  $z^2$ -dependence of pseudo-ITD: gauge link  $\hat{E}(0, z; A)$
- It has specific ultraviolet divergences
- Use Polyakov regularization  $1/z^2 \rightarrow 1/(z^2 - a^2)$  for gluon propagator in coordinate space
- Effect of the UV cut-off  $a$  is similar to that of the lattice spacing
- At one loop, link-related UV singular terms have the structure

$$\Gamma_{\text{UV}}(z_3, a) \sim -\frac{\alpha_s}{2\pi} C_F \left[ 2 \frac{|z_3|}{a} \tan^{-1} \left( \frac{|z_3|}{a} \right) - 2 \ln \left( 1 + \frac{z_3^2}{a^2} \right) \right]$$

- For fixed  $a$ , these terms vanish when  $z_3 \rightarrow 0$
- No violation of quark number conservation

### Evolution in lattice data

Data

Building  $\overline{MS}$  ITD

Results

### Summary

- Addition due to UV singular terms

$$Q^{\text{UV}}(y, P) = \int_{-1}^1 dx R^{\text{UV}}(y-x; a) f(x),$$

- Kernel  $R_{\text{UV}}(y-x; a)$  is given by

$$R^{\text{UV}}(y-x; a) = \frac{P}{2\pi} \int_{-\infty}^{\infty} dz_3 e^{-i(y-x)Pz_3} \Gamma_{\text{UV}}(z_3, a)$$

- Take  $\ln(1 + z_3^2/a^2)$  “vertex” term. Its Fourier transform gives

$$R_V(y, x; Pa) \sim -\frac{1}{|y-x|} e^{-|y-x|Pa} - \delta(y-x) \int_{-\infty}^{\infty} \frac{d\zeta}{|y-\zeta|} e^{-|y-\zeta|Pa}$$

- Taking  $a = 0$  gives  $\sim 1/|y-x|$  term similar to that appearing in the evolution-related kernel
- However, for  $a = 0$  the  $\zeta$ -integral accompanying the  $\delta(y-x)$  term diverges when  $\zeta \rightarrow \pm\infty$
- Need to keep nonzero  $a$  to have the exponential suppression factor that guarantees that  $R_V(y, x; Pa)$  is given by a mathematically well-defined expression

### Evolution in lattice data

Data

Building  $\overline{MS}$  ITD

Results

### Summary

- Structure of factorization for DIS in Feynman gauge
- Gluon insertions generate gauge link  $\hat{E}(0, z; A)$
- Quark self-energy diagram is not factorized as  $S^c(z) \times \langle AA \rangle$
- Operator  $\bar{\psi}(0)\hat{E}(0, z; A)\psi(z)$  should be accompanied by “no  $AA$  contractions”
- Link self-energy diagrams and UV-singular parts of vertex diagrams should be excluded together with associated  $z_3^2$ -dependence
- It is not sufficient just to subtract UV divergences
- Easy way out: consider reduced pseudo-ITD

$$\mathfrak{M}(\nu, z_3^2) \equiv \frac{\mathcal{M}(\nu, z_3^2)}{\mathcal{M}(0, z_3^2)}$$

- $\mathfrak{M}(\nu, z_3^2)$  has finite  $a \rightarrow 0$  limit

### Evolution in lattice data

Data

Building  $\overline{MS}$  ITD

Results

### Summary

- Reduced pseudo-ITD  $\mathfrak{M}(\nu, z_3^2)$  is a physical observable (like, say, DIS structure functions)
- No need to specify renormalization scheme, scale, etc.
- $\mathfrak{M}(\nu, z_3^2)$  is singular in  $z_3 \rightarrow 0$  limit,  $\ln z_3^2$  terms reflect perturbative evolution
- At one loop (with mass-type IR regularization)

$$\mathfrak{M}(\nu, z_3^2) = \mathfrak{M}^{\text{soft}}(\nu, 0) - \frac{\alpha_s}{2\pi} C_F \int_0^1 dw \left\{ \frac{1+w^2}{1-w} \left[ \ln \left( z_3^2 m^2 \frac{e^{2\gamma_E}}{4} \right) + 1 \right] + 4 \frac{\ln(1-w)}{1-w} \right\} \left[ \mathfrak{M}^{\text{soft}}(w\nu, 0) - \mathfrak{M}^{\text{soft}}(\nu, 0) \right]$$

- For light-cone PDF, one should take  $z^2 = 0$  and use some scheme for resulting UV divergence, say,  $\overline{MS}$
- Ioffe-time distribution  $\mathcal{I}(\nu, \mu^2)$  is UV scheme and scale dependent

$$\mathcal{I}(\nu, \mu^2) = \int_{-1}^1 dx e^{ix\nu} f(x, \mu^2)$$

- At one loop (with the same mass-type IR regularization)

$$\mathcal{I}(\nu, \mu^2) = \mathfrak{M}^{\text{soft}}(\nu, 0) - \frac{\alpha_s}{2\pi} C_F \int_0^1 dw \left[ \mathfrak{M}^{\text{soft}}(w\nu, 0) - \mathfrak{M}^{\text{soft}}(\nu, 0) \right] \times \left\{ \frac{1+w^2}{1-w} \ln(m^2/\mu^2) + 2(1-w) \right\}$$

### Evolution in lattice data

Data

Building  $\overline{\text{MS}}$  ITD

Results

### Summary

- Writing  $\overline{\text{MS}}$  ITD in terms of reduced pseudo-ITD

$$\mathcal{I}(\nu, \mu^2) = \mathfrak{M}(\nu, z_3^2) + \frac{\alpha_s}{2\pi} C_F \int_0^1 dw \mathfrak{M}(w\nu, z_3^2) \times \left\{ B(w) \left[ \ln \left( z_3^2 \mu^2 \frac{e^{2\gamma_E}}{4} \right) + 1 \right] + \left[ 4 \frac{\ln(1-w)}{1-w} - 2(1-w) \right]_+ \right\}$$

- Altarelli-Parisi kernel  $B(w) = [(1+w^2)/(1-w)]_+$
- Multiplicative scale difference between  $z^2$  and  $\overline{\text{MS}}$  cut-offs  $\mu^2 = 4e^{-2\gamma_E}/z_3^2$
- Simple rescaling relation is modified when all terms are taken into account

- Term with  $[\ln(1-w)]/(1-w)$  produces large negative contribution
- In Feynman gauge, it comes from vertex diagrams
- Gluon is attached to running  $tz_3$  position on the link
- $z_3$ -dependence is generated then by effective scale smaller than  $z_3$

## Evolution in lattice data

Data

Building  $\overline{MS}$  ITD

Results

## Summary

- Exploratory lattice study of reduced pseudo-ITD  $\mathfrak{M}(\nu, z_3^2)$  for the valence  $u_v - d_v$  parton distribution in the nucleon [Orginos et al. 2017]
- When plotted as function of  $\nu$ , data both for real and imaginary parts lie close to respective universal curves
- Data show no polynomial  $z_3$ -dependence for large  $z_3$  though  $z_3^2/a^2$  changes from 1 to  $\sim 200$
- Apparently no higher-twist terms in the reduced pseudo-ITD
- Real part corresponds to the cosine Fourier transform of  $q_v(x) = u_v(x) - d_v(x)$

$$\Re(\nu) \equiv \text{Re } \mathfrak{M}(\nu) = \int_0^1 dx \cos(\nu x) q_v(x)$$

- Overall curve corresponds to the function

$$f(x) = \frac{315}{32} \sqrt{x}(1-x)^3$$

- Obtained by forming cosine Fourier transforms of  $x^a(1-x)^b$ -type functions and fitting  $a, b$
- Shape is dominated by points with smaller values of  $\text{Re } \mathfrak{M}(\nu, z_3^2)$ .

### Evolution in lattice data

Data  
 Building  $\overline{\text{MS}}$  ITD  
 Results

### Summary

- Points corresponding to  $7a \leq z_3 \leq 13a$  values
- Some scatter for points with  $\nu \gtrsim 10$
- Otherwise, practically all the points lie on the universal curve based on  $f(x)$ .
- No  $z_3$ -evolution visible in large- $z_3$  data
- Points in  $a \leq z_3 \leq 6a$  region
- All points lie higher than universal curve
- Perturbative evolution increases real part of the pseudo-ITD when  $z_3$  decreases
- Conjecture that the observed higher values of  $\Re$  for smaller- $z_3$  points may be a consequence of evolution
- $z_3$ -dependence of the lattice points for “magic” Ioffe-time value  $\nu = 3\pi/4$
- Shape of eye-ball fit line is  $\Gamma(0, z_3^2/30a^2)$
- “Perturbative”  $\ln(1/z_3^2)$  behavior for small  $z_3$ , rapidly vanishes for  $z_3 > 6a$
- $\Re(\nu, z_3^2)$  decreases when  $z_3$  increases

Results

## Summary

- Data show a logarithmic evolution behavior in small  $z_3$  region
- Starts to visibly deviate from a pure logarithmic  $\ln z_3^2$  pattern for  $z_3 \gtrsim 5a$
- This sets the boundary  $z_3 \leq 4a$  on the “logarithmic region”
- “Evolution” part of 1-loop correction

$$\mathcal{I}_R^{\text{ev}}(\nu, \mu^2) = \Re(\nu, z_3^2) + \frac{\alpha_s}{2\pi} C_F \int_0^1 dw \Re(w\nu, z_3^2) B(w) \ln \left( z_3^2 \mu^2 \frac{e^{2\gamma_E}}{4} \right)$$

- For  $z_3 = 2e^{-\gamma_E}/\mu$ , the logarithm vanishes, and we have

$$\mathcal{I}_R^{\text{ev}}(\nu, \mu^2) = \Re(\nu, (2e^{-\gamma_E}/\mu)^2) = \Re(\nu, (1.12/\mu)^2)$$

- This happens only if, for some  $\alpha_s$ , the  $\ln z_3^2$ -dependence of the 1-loop term cancels actual  $z_3^2$ -dependence of the data, visible as scatter in the data
- Fitted value:  $\alpha_s/\pi \approx 0.1$
- Remaining part of  $\mathcal{I}(\nu, \mu^2)$  is due to corrections beyond the leading log approximation

$$\begin{aligned} \mathcal{I}_R^{\text{NL}}(\nu) &= \frac{\alpha_s}{2\pi} C_F \int_0^1 dw \Re_f(w\nu) \left\{ B(w) + \left[ 4 \frac{\ln(1-w)}{1-w} - 2(1-w) \right]_+ \right\} \\ &\equiv \frac{\alpha_s}{2\pi} C_F [B \otimes \Re_f + L \otimes \Re_f] \end{aligned}$$

Results

Summary

- $L \otimes \mathfrak{R}_f$  is negative and rather large
- In  $\nu < 5$  region,  $L \otimes \mathfrak{R}_f \approx -3.5B \otimes \mathfrak{R}_v$
- Combined effect is close to LLA evolution with modified rescaling factor

$$\mathcal{I}_R(\nu, \mu^2) \approx \mathfrak{R}(\nu, (4/\mu)^2)$$

- Actual calculations should be done using “exact” formula
- We choose  $\mu = 1/a$  which, at lattice spacing of 0.093 fm is  $\approx 2.15$  GeV
- Using  $\alpha_s/\pi = 0.1$  and  $z_3 \leq 4a$  data, we generate the points for  $\mathcal{I}_R(\nu, (1/a)^2)$
- Upper curve corresponds to the ITD of the CJ15 global fit PDF for  $\mu = 2.15$  GeV

- Evolved points are close to some universal curve with a rather small scatter
- The curve itself corresponds to the cosine transform of a normalized  $\sim x^a(1-x)^b$  distribution with  $a = 0.35$  and  $b = 3$

## Summary

- Analyzed nonperturbative structure of quasi-PDFs  $Q(y, P)$  using their relation to pseudo-ITDs and TMDs
- Shown that  $(\Lambda^2/P^2)^n$  expansion for  $Q(y, P)$  involves generalized functions
- Using factorized models for TMDs, studied rate of approach of quasi-PDFs  $Q(y, P)$  to PDFs  $f(y)$  when  $P \rightarrow \infty$
- Demonstrated that target-mass corrections are a small part of  $k_{\perp}^2$  corrections artificially singled out from them
- Analyzed perturbative structure of quasi-PDFs using their relation to pseudo-ITDs and TMDs
- Shown that evolution  $\log \ln z_3^2$  gives  $\sim 1/y^2$  behavior of qPDFs for large  $y$
- $\sim 1/y$  terms come from UV singular link-related terms
- Argued that link-related terms should be “exterminated”
- Proposed to use reduced pseudo-ITD
- Studied evolution of exploratory lattice data for reduced pseudo-ITD
