Gluon PDFs

- Experimentally, we work with hadrons
- Theoretically, we work with quarks

- Can be described in coordinate or momentum space

$$\langle p | \phi(0) \phi(z) | p \rangle \equiv M(z, p) = \frac{1}{\pi^2} \int d^4 k e^{-ikz} \chi(k, p)$$

- Concept of PDFs does not rely on spin complications

Gluon PDFs

- In momentum representation: PDF $f(x)$ gives probability that parton carries fraction xp^+ of hadron momentum component p^+

- In coordinate representation: PDF $f(x)$ is given by Fourier transform of matrix element $M(z, p)$ on the light cone $z^2 = 0$
- By Lorentz invariance, $M(z, p)$ is a function of (zp) and z^2 , i.e. (zp) only when $z^2 = 0$
- Ioffe time ν : taking $z = z^-$ we have $(zp) = p^+ z^- \equiv -\nu$

$$f(x) = \frac{p^+}{2\pi} \int_{-\infty}^{\infty} dz^- e^{ixp^+ z^-} M(z^-, p) = \frac{1}{2\pi} \int_{-\infty}^{\infty} d\nu e^{-ix\nu} \mathcal{I}(\nu)$$

- Ioffe-time distribution $\mathcal{I}(\nu)$
- Observation: ν -dependence governs x -dependence

Gluon PDFs

- Lattice is Euclidean: no lightcone separations
- Take z off the light cone: $z^2 < 0$
- By Lorentz invariance
 $M(z, p) = \mathcal{M}(-(pz), -z^2)$
- Ioffe time $\nu = -(pz)$
- $\mathcal{M}(\nu, -z^2)$: pseudo-ITD
- **Pseudo** \equiv off the light cone, $z^2 \neq 0$

- Using Schwinger's α -representation, it is possible to show that, for **any** contributing Feynman diagram, for **arbitrary** z^2 and **arbitrary** p^2

$$\mathcal{M}(\nu, -z^2) = \int_{-1}^1 dx e^{ix\nu} \mathcal{P}(x, -z^2)$$

- $\mathcal{P}(x, -z^2) =$ **pseudo-PDF**, or PDF off the light cone
- $e^{ix\nu} = e^{-ix(pz)}$: decomposition over plane waves with momentum $k = xp$
- “Canonical” limits $-1 \leq x \leq 1$
- Negative x correspond to anti-particles
- Note: x is Lorentz invariant: same “on” and “off” LC

 Gluon PDFs

- On the lattice: cannot take “ z ” on the light cone
Need to take it off the light cone!
- Take $z = \{0, 0, 0, z_3\}$ (X. Ji (2013), quasi-PDF approach, $p_3 \rightarrow \infty$)
- Pseudo-PDF approach is based on **key observation**:
It does not matter if ν was obtained as $-(p_+ z_-)$ or as $p_3 z_3$:
the function $\mathcal{M}(\nu, -z^2)$ is the same!
- For $z = z_3$, we have $\nu = p_3 z_3$ and $-z^2 = z_3^2$
- Analogy with DIS structure functions $W(\omega, Q^2)$
- $\omega = 1/x$ and
- $1/Q$ characterizes “probing distance”
- In pseudo-PDFs, z_3 is the “probing distance” literally
- Important to realize: dependence of $M(z, p)$ on z
comes (1) through dependence on (pz)
and (2) remaining dependence on z for a fixed (pz)
- Pseudo-PDF strategy: map lattice data on $M(z_3, p)$
in terms of ν and z_3^2 and extrapolate $\mathcal{M}(\nu, z_3^2)$ to $z_3^2 = 0$
- Need to understand various types of z^2 -dependence of $\mathcal{M}(\nu, z_3^2)$

Gluon PDFs

- Specific source of z^2 -dependence in QCD: gauge link $\hat{E}(0, z; A) = P \exp\{ig \int_0^z A^\mu dx_\mu\}$
- It comes together with ultraviolet divergences: linear $\sim z_3/a$ and logarithmic $\ln(z_3^2/a^2)$, where $a \sim$ UV cut-off, e.g. lattice spacing a_L
- At one loop, UV terms have been calculated in lattice perturbation theory (Ji et al., 2016)
- Result close to that obtained using Polyakov regularization $1/z^2 \rightarrow 1/(z^2 - a^2)$ for gluon propagator in coordinate space, with $a = a_L/\pi$

$$\Gamma_{\text{UV}}(z_3, a) \sim -\frac{\alpha_s}{2\pi} C_F \left[2 \frac{|z_3|}{a} \tan^{-1} \left(\frac{|z_3|}{a} \right) - \ln \left(1 + \frac{z_3^2}{a^2} \right) \right]$$

- 1-loop result exponentiates in higher orders, producing $\sim e^{-2\alpha_s z_3/3a}$ factor for large z_3
- Vertex corrections produce extra $\frac{\alpha_s}{2\pi} C_F \ln(1 + z_3^2/a^2)$ term exponentiating in higher orders

Gluon PDFs

- Link-related UV divergences have the same structure as in HQET
- They are multiplicatively renormalizable (Qiu et al. , Ji et al. , Green et al. 2017)
- UV regulator a appears only in the combination z_3/a
- UV-sensitive terms form a factor $Z(z_3^2/a^2)$
- This factor is an artifact of having a non-lightlike z : $Z = 1$ on the light cone
- It has nothing to do with the usual PDFs
- We should build modified function $Z^{-1}(z_3^2/a^2)\mathcal{M}(\nu, z_3^2; a)$
- To do this, one should know the $Z(z_3^2/a^2)$ factor
- Easier way out: consider reduced pseudo-ITD

$$\mathfrak{M}(\nu, z_3^2) \equiv \frac{\mathcal{M}(\nu, z_3^2)}{\mathcal{M}(0, z_3^2)} = \lim_{a \rightarrow 0} \frac{\mathcal{M}(\nu, z_3^2; a)}{\mathcal{M}(0, z_3^2; a)}$$

- $Z(z_3^2/a^2)$ factors cancel, and $\mathfrak{M}(\nu, z_3^2)$ has finite $a \rightarrow 0$ limit

- Exploratory study in quenched approximation (Orginos et al. 2017), is still the most precise pPDF calculation
- Allows to study basic aspects of hadron dynamics on the lattice
- Rest-frame density $\mathcal{M}(0, z_3^2)$ is produced by data at $p_3 = 0$

- $\mathcal{M}(0, z_3^2)$ serves as the UV renormalization factor
- Red line is exponential of 1-loop result for link self-energy and vertex corrections with $\alpha_s = 0.19$
- Very strong effect from $Z(z_3^2) \sim e^{-c|z_3|/a}$

 Gluon PDFs

- From phenomenology: $f(x, k_\perp) \sim e^{-k_\perp^2/\Lambda^2} f(x)$, with $\Lambda \sim 300$ MeV
- Reflects finite hadron size
- Translates into $\mathcal{P}(x, z_3^2) \sim e^{-z_3^2\Lambda^2/4} f(x)$ for pPDF
- Translates into $\mathcal{M}(\nu, z_3^2) \sim e^{-z_3^2\Lambda^2/4} I(\nu)$ for pITD

- Small correction compared to $Z(z_3^2)$
- Also: cancels in the $\mathcal{M}(\nu, z_3^2)/\mathcal{M}(0, z_3^2)$ ratio
- If $\mathcal{M}(\nu, z_3^2) \sim e^{-z_3^2\Lambda^2/4} I(\nu)$ is not perfect, some residual HT terms $\sim z_3^2\lambda^2$ may remain, with $\lambda \lesssim 100$ MeV
- Strategy: fit residual HT from data

Gluon PDFs

- Exploratory lattice study of reduced pseudo-ITD $\mathfrak{M}(\nu, z_3^2)$ for the valence $u_v - d_v$ parton distribution in the nucleon [Orginos et al. 2017]
- Lattice QCD calculations in quenched approximation
- $32^3 \times 64$ lattices, lattice spacing $a = 0.093$ fm
- Pion mass 601(1) MeV and nucleon mass 1411(4) MeV
- Six lattice momenta p_i ($2\pi/L$), with 2.5 GeV maximal momentum
- Relation between PDF and ITD involves $e^{ix\nu} = \cos x\nu + i \sin x\nu$

$$\mathcal{I}(\nu) = \int_{-\infty}^{\infty} d\nu e^{ix\nu} f(x)$$

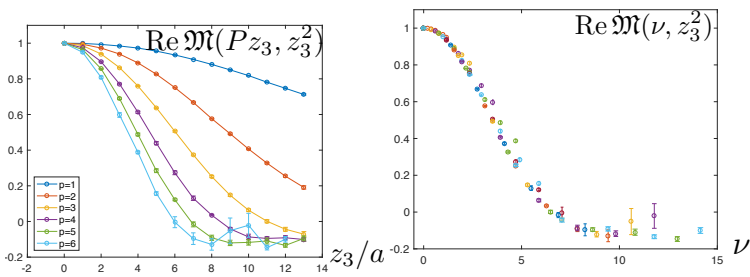

- Real part of ITD $\mathcal{I}(\nu)$ corresponds to cosine Fourier transform of $q_v(x) = u_v(x) - d_v(x)$

$$\mathcal{R}(\nu) \equiv \text{Re} \mathcal{I}(\nu) = \int_0^1 dx \cos(\nu x) q_v(x)$$

- On the lattice, we extract the reduced pseudo-ITD

$$\mathfrak{M}(\nu, z_3^2) \equiv \frac{\mathcal{M}(\nu, z_3^2)}{\mathcal{M}(0, z_3^2)}$$

- Left: Real part of the ratio $\mathcal{M}(Pz_3, z_3^2)/\mathcal{M}(0, z_3^2)$ as a function of z_3
- Taken at six values of $P \Rightarrow$ curves have Gaussian-like shape
- $\Rightarrow Z(z_3^2)$ link factor cancels in the ratio

- Right: Same data, as functions of $\nu = Pz_3$ (z_3^2 varies from point to point)
- Data practically fall on the same universal curve
- Data show no polynomial z_3 -dependence for large z_3 though z_3^2/a^2 changes from 1 to ~ 200
- Apparently no higher-twist terms in the reduced pseudo-ITD

 Range of applicability
 Dynamic fermions
 Gluon PDFs

- After cancellation of z_3^2 -dependence from $Z(z_3^2)$ and (hopefully) HT:
- Remaining z_3^2 -dependence corresponds to perturbative (DGLAP) evolution
- At one loop,

$$\mathfrak{M}^{(1)}(\nu, z_3^2) = -\frac{\alpha_s}{2\pi} C_F \ln(z_3^2) \int_0^1 du B(u) \mathfrak{M}^{(0)}(u\nu)$$

- Altarelli-Parisi (AP) evolution kernel

$$B(u) = \left[\frac{1+u^2}{1-u} \right]_+$$

- Example of z_3 -dependence for $\nu = 12\pi/16 \approx 2.36$
- “Magic” Ioffe-time pz value:
 $12 = 1 \times 12 = 2 \times 6 = 3 \times 4 = 4 \times 3 = 6 \times 2$
 can be obtained for 5 different z 's
- Shows “perturbative” $\ln(1/z_3^2)$ for small z_3
- Close to a constant for $z_3 > 6a$
- Finite-size (“HT”) effect in 1-loop terms

- Matching condition between reduced pseudo-ITD and $\overline{\text{MS}}$ ITD (Y. Zhao 2017, A.R. 2017)

$$\mathfrak{M}(\nu, z_3^2) = \mathcal{I}(\nu, \mu^2) - \frac{\alpha_s(\mu)}{2\pi} C_F \int_0^1 dw \mathcal{I}(w\nu, \mu^2) \times \left\{ B(w) \left[\ln \left(z_3^2 \mu^2 \frac{e^{2\gamma_E}}{4} \right) + 1 \right] + \left[4 \frac{\ln(1-w)}{1-w} - 2(1-w) \right]_+ \right\}$$

- Building $\overline{\text{MS}}$ ITD

- Points in $a \leq z_3 \leq 4a$ region $\mu = 1/a_L \approx 2.15 \text{ GeV}$, $\alpha_s/\pi = 0.1$
- Evolved points have a rather small scatter
- The curve corresponds to the cosine transform of a normalized $\sim x^a(1-x)^b$ distribution with $a = 0.35$ and $b = 3$
- Upper curve: ITD of the CJ15 global fit PDF for $\mu = 2.15 \text{ GeV}$

Gluon PDFs

- Rule of thumb: use perturbation theory when correction is small

$$\mathfrak{M}(\nu, z_3^2) = \mathcal{I}(\nu, \mu^2) - \frac{\alpha_s(\mu)}{2\pi} C_F \int_0^1 dw \mathcal{I}(w\nu, \mu^2) \times \left\{ B(w) \left[\ln \left(z_3^2 \mu^2 \frac{e^{2\gamma_E}}{4} \right) + 1 \right] + \left[4 \frac{\ln(1-w)}{1-w} - 2(1-w) \right]_+ \right\}$$

- Factor $e^{2\gamma_E}/4 \approx 1/1.2$ relates scales in $\overline{\text{MS}}$ and “ z^2 ” scheme
- Suggesting $\Lambda_{z^2} \approx \Lambda_{\overline{\text{MS}}}/1.1$
- Next step: $\mathfrak{M}(\nu, z_3^2) = \mathcal{I}(\nu, \mu^2)$ when α_s correction is zero
- This happens when $\mu \approx 4/z_3$, because of large correction from $\ln(1-w)$
- Numerically: $\mathcal{I}(\nu, (2 \text{ GeV})^2) \approx \mathfrak{M}(\nu, (0.4 \text{ fm})^2)$
- Take $\mu = 1 \text{ GeV}$: $\mathcal{I}(\nu, (1 \text{ GeV})^2) \approx \mathfrak{M}(\nu, (0.8 \text{ fm})^2)$
- \Rightarrow for $a_L \sim 0.1 \text{ fm}$, PT is formally applicable till $z_3 \sim 8a_L$
- Caution: data show deviation from $\ln(z_3^2)$ for $z_3 \gtrsim 5a_L$
- Finite hadron size effects in $\mathcal{O}(\alpha_s)$ terms

- Z-factor $\text{Re } \mathcal{M}(0, z_3^2)$ is clearly a function of z_3/a_L

- α_s decreases with a_L . Check if it is $\alpha_s(1/a_L)$
- Since $\alpha_s(1/a_L) = 2\pi/[b_0 \ln(1/a_L \Lambda)]$, we plot $1/\alpha_s$ versus $\ln(1/a_L)$
- Fit corresponds to $\Lambda = 200 \text{ MeV}$, and $\beta_0 = 11.4$
- Since $\beta_0 = 11 - 2N_f/3$, contribution of quark loops into α_s in this simulation is not visible
- Comparison with global fits
- Lattice result is smaller for small x
- Pion mass was taken 440 MeV
- Too large to give realistic PDF for small x
- Higher twists $\lesssim 0.15 \Lambda_{\text{QCD}}^2 z_3^2$

- Correlator of two gluon fields has 4 indices

$$M_{\mu\alpha;\nu\beta}(z, p) \equiv \langle p | G_{\mu\alpha}(z) [z, 0] G_{\nu\beta}(0) | p \rangle$$

- Need 6 invariant amplitudes $\mathcal{M}(\nu, z^2)$

$$\begin{aligned} M_{\mu\alpha;\nu\beta}(z, p) = & (g_{\mu\nu} p_\alpha p_\beta - g_{\mu\beta} p_\alpha p_\nu - g_{\alpha\nu} p_\mu p_\beta + g_{\alpha\beta} p_\mu p_\nu) \mathcal{M}_{pp}(\nu, z^2) \\ & + (g_{\mu\nu} z_\alpha z_\beta - g_{\mu\beta} z_\alpha z_\nu - g_{\alpha\nu} z_\mu z_\beta + g_{\alpha\beta} z_\mu z_\nu) \mathcal{M}_{zz}(\nu, z^2) \\ & + (g_{\mu\nu} z_\alpha p_\beta - g_{\mu\beta} z_\alpha p_\nu - g_{\alpha\nu} z_\mu p_\beta + g_{\alpha\beta} z_\mu p_\nu) \mathcal{M}_{zp}(\nu, z^2) \\ & + (g_{\mu\nu} p_\alpha z_\beta - g_{\mu\beta} p_\alpha z_\nu - g_{\alpha\nu} p_\mu z_\beta + g_{\alpha\beta} p_\mu z_\nu) \mathcal{M}_{pz}(\nu, z^2) \\ & + (p_\mu z_\alpha - p_\alpha z_\mu) (p_\nu z_\beta - p_\beta z_\nu) \mathcal{M}_{ppzz}(\nu, z^2) \\ & + (g_{\mu\nu} g_{\alpha\beta} - g_{\mu\beta} g_{\alpha\nu}) \mathcal{M}_{gg}(\nu, z^2) \end{aligned}$$

- “Light-cone” gluon distribution $f_g(x)$ is defined through the convolution $g^{\alpha\beta} M_{+\alpha;\beta+}(z, p)$, with z taken in the light-cone “minus” direction, $z = z_-$:

$$g^{\alpha\beta} M_{+\alpha;\beta+}(z_-, p) = p_+^2 \int_{-1}^1 dx e^{ixp_+ + z_-} x f_g(x)$$

- In terms of invariant amplitudes

$$g^{\alpha\beta} M_{+\alpha;\beta+}(z_-, p) = -2p_+^2 \mathcal{M}_{pp}(\nu, 0)$$

- Strategy is to choose matrix elements $M_{\mu\alpha;\lambda\beta}$ that contain \mathcal{M}_{pp} in their parametrization – and ideally nothing else!
- Split the “+” components onto sum of space- and time-components
- Due to antisymmetry of $G_{\rho\sigma}$ with respect to its indices, $g^{\alpha\beta} M_{+\alpha;\beta+}(z, p)$ includes summation over transverse indices $i, j = 1, 2$ only

$$g^{ij} M_{+i;j+} = -M_{+1;1+} - M_{+2;2+} = M_{0i;0i} + M_{3i;3i} + (M_{0i;3i} + M_{3i;0i})$$

- Decomposition of these matrix elements in invariant amplitudes

$$M_{0i;i0} = 2p_0^2 \mathcal{M}_{pp} + 2\mathcal{M}_{gg}$$

$$M_{3i;i3} = 2p_3^2 \mathcal{M}_{pp} + 2z_3^2 \mathcal{M}_{zz} + 2z_3 p_3 (\mathcal{M}_{zp} + \mathcal{M}_{pz}) - 2\mathcal{M}_{gg}$$

$$M_{0i;i3} = 2p_0 (p_3 \mathcal{M}_{pp} + z_3 \mathcal{M}_{pz})$$

$$M_{3i;i0} = 2p_0 (p_3 \mathcal{M}_{pp} + z_3 \mathcal{M}_{zp})$$

- All contain the \mathcal{M}_{pp} , though with different kinematical factors
- Unfortunately, none of them is just \mathcal{M}_{pp}
- Fortunately, $M_{ji;ij} = -2\mathcal{M}_{gg}$
- Hence, the combination

$$M_{0i;i0} + M_{ji;ij} = 2p_0^2 \mathcal{M}_{pp}$$

may be used for extraction of the twist-2 function \mathcal{M}_{pp}

 Gluon PDFs

- In the polarized gluon case, tensor structures may be built from 3 vectors: z_μ , p_μ and s_μ
- As a result, one deals with 12 invariant amplitudes
- Combination, similar to that used in unpolarized case

$$\widetilde{M}_{0i;0i}(z, p) + \widetilde{M}_{ij;ij}(z, p) = -2p_z p_0 \widetilde{\mathcal{M}}_{sp}^{(+)}(\nu, z^2) + 2p_0^3 z \widetilde{\mathcal{M}}_{pp}(\nu, z^2)$$

- The polarized gluon PDF is determined by the Ioffe-time distribution

$$-i\widetilde{\mathcal{I}}_p(\nu) \equiv \widetilde{\mathcal{M}}_{ps}^{(+)}(\nu) - \nu \widetilde{\mathcal{M}}_{pp}(\nu)$$

- Matrix element $\widetilde{M}_{0i;0i}(z, p) + \widetilde{M}_{ij;ij}(z, p)$ has a “slightly” different structure

$$\widetilde{\mathfrak{M}}(\nu, z^2) = \left[\widetilde{\mathcal{M}}_{sp}^{(+)}(\nu, z^2) - \nu \widetilde{\mathcal{M}}_{pp}(\nu, z^2) \right] - \frac{m_p^2}{p_z^2} \nu \widetilde{\mathcal{M}}_{pp}(\nu, z^2)$$

- The goal is to eliminate the $\mathcal{O}(m_p^2/p_z^2)$ contamination term and extract $\widetilde{\mathcal{M}}_{sp}^{(+)}(\nu, z^2) - \nu \widetilde{\mathcal{M}}_{pp}(\nu, z^2)$

Gluon PDFs

- Pseudodistribution approach allows to study hadron structure in a way similar to experimental study of DIS
- Instead of structure functions $W(x, Q^2)$, we study Ioffe-time distributions $\mathcal{M}(\nu, z_3^2)$
- Ioffe time ν is Fourier-conjugate to x
- z_3 is probing scale, like $1/Q$ in DIS
- Detailed studies of ν - and z_3^2 -dependence decipher subtleties of hadron dynamics
- Existing lattice extractions of PDFs still play exploratory role
- The current goal is to check that lattice methods give reasonable results for PDFs known experimentally
- The future goal is to get the functions which are not directly accessible by experiment: a key example is given by GPDs $H(x, \xi; t)$
